

ON KUIPER'S QUESTION WHETHER TAUT SUBMANIFOLDS ARE ALGEBRAIC

THOMAS E. CECIL, QUO-SHIN CHI, AND GARY R. JENSEN

ABSTRACT. We prove that any connected proper Dupin hypersurface in \mathbf{R}^n is analytic algebraic and is an open subset of a connected component of an irreducible algebraic set. From this we also prove that every taut submanifold of dimension $m \leq 4$ is algebraic by exploring a finiteness condition.

1. INTRODUCTION

An embedding f of a compact, connected manifold M into Euclidean space \mathbf{R}^n is *taut* if every nondegenerate (Morse) Euclidean distance function, $L_p : M \rightarrow \mathbf{R}$, $L_p(x) = d(f(x), p)^2$, $p \in \mathbf{R}^n$, has $\beta(M, \mathbf{Z}_2)$ critical points on M , where $\beta(M, \mathbf{Z}_2)$ is the sum of the \mathbf{Z}_2 -Betti numbers of M . That is, L_p is a perfect Morse function on M .

We can also consider taut embeddings into S^n , in which case we use spherical distance functions instead of Euclidean distance functions. Tautness is preserved by stereographic projection, and so the theories in the two ambient spaces are essentially the same.

A connected hypersurface M in \mathbf{R}^n is said to be *Dupin* if along each curvature surface of M , the corresponding principal curvature is constant. M is called *proper Dupin* if, in addition, the number g of distinct principal curvatures is constant on M . Thorbergsson [17] proved that a compact proper Dupin hypersurface must be taut.

Many taut submanifolds, such as the cyclides of Dupin [1], Veronese manifolds [3], and isoparametric submanifolds [16], are known to be algebraic, and in 1984 Kuiper [7] asked whether all taut submanifolds of \mathbf{R}^n must be real algebraic. In the 1980's, the affirmative answer to this question was widely thought to be true, but a proof was never

published. In particular, in 1984 Ulrich Pinkall sent a sketch [10] of a proof that proper Dupin hypersurfaces are algebraic in a letter to Tom Cecil, and we wish to thank Professor Pinkall for allowing us to use his approach to the problem in our work in this paper.

Pinkall's sketch led us to the local parametrization (3.7) of a general proper Dupin hypersurface. We then used ideas from real algebraic geometry to show that a connected proper Dupin hypersurface is contained in a connected component of an irreducible algebraic subset of \mathbf{R}^n . There are still issues to be resolved to settle this question of Kuiper's, however, because arbitrary taut submanifolds are Dupin, but not necessarily proper Dupin [11]. In this paper, we prove that the answer to Kuiper's question is affirmative for manifolds of dimension $m \leq 4$. (The result in dimensions $m \leq 2$ is due to Banchoff [1].)

2. ALGEBRAIC PRELIMINARIES

A *semi-algebraic subset* of \mathbf{R}^n is one which is a finite union of sets of the form $\cap_j \{x \in \mathbf{R}^n : F_j(x) * 0\}$, where $*$ is either $<$ or $=$, F_j is a polynomial over \mathbf{R}^n , and the intersection is finite.

It follows from the definition that the complement of a semi-algebraic set is semi-algebraic, and hence a semi-algebraic set take away another semi-algebraic set leaves a semi-algebraic set. Moreover, the projection $\pi : \mathbf{R}^n \rightarrow \mathbf{R}^k$ sending $x \in \mathbf{R}^n$ to its first k coordinates maps a semi-algebraic set to a semi-algebraic set. As a corollary, the (topological) closure and interior of a semi-algebraic set are semi-algebraic.

A map $f : S \subset \mathbf{R}^n \rightarrow \mathbf{R}^k$ is *semi-algebraic* if its graph in $\mathbf{R}^n \times \mathbf{R}^k$ is a semi-algebraic set. As a result, the image of a semi-algebraic map $f : S \subset \mathbf{R}^n \rightarrow \mathbf{R}^k$ is semi-algebraic, via the composition $\text{graph}(f) \subset \mathbf{R}^n \times \mathbf{R}^k \rightarrow \mathbf{R}^k$, where the last map is the projection onto the second summand.

A *Nash function* is a C^∞ semi-algebraic map from an open semi-algebraic subset of \mathbf{R}^n to \mathbf{R} . A real analytic function f defined on an open semi-algebraic subset U of \mathbf{R}^n is *analytic algebraic* if it is a solution of a polynomial equation on U of the form,

$$(2.1) \quad a_0(x)f^s(x) + a_1(x)f^{s-1}(x) + \cdots + a_s(x) = 0,$$

where $a_0(x) \neq 0, a_1(x), \cdots, a_s(x)$ are polynomials over \mathbf{R}^n . A significant result in the subject is that these two concepts are equivalent [2, p. 165]). A slight generalization of the single-variable case [2, p. 54] shows that the partial derivatives of any Nash function are again Nash functions.

Let S be a semi-algebraic subset of \mathbf{R}^n . The *dimension* of S , denoted $\dim S$, is the dimension of the ring $R = \mathbf{R}[x^1, \cdots, x^n]/\mathcal{I}(S)$, the

quotient ring of the polynomial ring modulo the ideal generated by S . It is the maximal length of chains of prime ideals of R . As usual, when S is a semi-algebraic subset of \mathbf{R}^n that is a C^∞ submanifold of \mathbf{R}^n of dimension d , then $\dim S = d$ [2, p. 54].

We denote the topological closure of S by $\overline{S}^{\text{top}}$. Denote the Zariski closure of S by $\overline{S}^{\text{zar}}$. It is the smallest algebraic set containing S . The important property that plays a central role in our arguments to follow is that if S is a semi-algebraic subset of \mathbf{R}^n , then $\dim S = \dim(\overline{S}^{\text{top}}) = \dim(\overline{S}^{\text{zar}})$ [2, p. 50].

Lemma 1. *Let $M \subset \mathbf{R}^n$ be a connected analytic submanifold and let $U \subset M$ be a connected open subset of M . If U is a semi-algebraic subset of \mathbf{R}^n , then M is an open subset of a connected component of the irreducible algebraic set $\overline{U}^{\text{zar}}$.*

The proof makes use of the fact that the Zariski closure $\overline{U}^{\text{zar}}$ of U is irreducible, because $\mathcal{I}(\overline{U}^{\text{zar}}) = \mathcal{I}(U)$ is a prime ideal. Hence $M \subset \mathcal{Z}(\mathcal{I}(U)) = \overline{U}^{\text{zar}}$.

A semi-algebraic subset M of \mathbf{R}^m is a *Nash submanifold* of \mathbf{R}^m of dimension n if for every point p of M , there exists a Nash diffeomorphism ψ from an open semi-algebraic neighborhood U of the origin in \mathbf{R}^m into an open semi-algebraic neighborhood V of p in \mathbf{R}^m such that $\psi(0) = p$ and $\psi((\mathbf{R}^n \times \{0\}) \cap U) = M \cap V$. Here, by a *Nash diffeomorphism* ψ we mean the coordinate functions of ψ and ψ^{-1} are Nash functions.

Let M be a Nash submanifold of \mathbf{R}^m . A mapping $f : M \rightarrow \mathbf{R}$ is a *Nash mapping* if it is semi-algebraic, and for every ψ in the preceding definition, $f \circ \psi|_{\mathbf{R}^n \cap U}$ is a Nash function. As usual, if df is never zero at all points of $f^{-1}(p)$, then $f^{-1}(p)$ is a Nash submanifold. A sphere, for instance, is thus Nash.

The following lemma [8, p. 44] is crucial in our paper.

Lemma 2. *Let X be a closed semi-algebraic subset of \mathbf{R}^n of dimension d . If there is an open set U of X such that U is a C^∞ submanifold of dimension d in \mathbf{R}^n , then around each point p of U there is an open neighborhood $B \subset U$ that is a semi-algebraic subset of \mathbf{R}^n .*

3. PROPER DUPIN HYPERSURFACES ARE ALGEBRAIC

Let $f : M^{n-1} \rightarrow \mathbf{R}^n$ be a proper Dupin hypersurface. Suppose f has g principal curvatures $\kappa_1, \dots, \kappa_g$, with multiplicities m_1, \dots, m_g . Let $\mathcal{A}_1, \dots, \mathcal{A}_g$ be a partition of the set $\{1, \dots, n-1\}$ into disjoint subsets for which the cardinality of \mathcal{A}_i is the multiplicity m_i , for $i = 1, \dots, g$.

For any point $p \in M$, the i^{th} curvature surface through p is either an open subset of a sphere of dimension m_i in \mathbf{R}^n or an open subset of a plane of dimension m_i [3]. Inversion in a sphere whose center does not lie on the union of all these spheres and planes will transform all curvature surfaces of $f(M)$ to open subsets of spheres. Thus, we may assume that all curvature surfaces of f are open subsets of spheres of the appropriate dimensions.

Denote the center of the sphere of dimension m_i containing the i^{th} curvature surface through $f(p)$ by $c_i(p) \in \mathbf{R}^n$, and its radius by $r_i(p) = |f(p) - c_i(p)|$. It is well known that $c_i(p)$ is rationally determined by $j_p^3(f)$, the 3-jet of f at p [3, pp. 140–147], [12]. If $e_a(p)$, for $a \in \mathcal{A}_i$, form an orthonormal basis of principal vectors for the i^{th} principal curvature, then they are determined by $j_p^2(f)$, the 2-jet of f at p .

Since the sphere is Nash, for any point $p \in M$, there is an analytic algebraic parametrization of an open subset about $f(p)$ of the i^{th} curvature surface through $f(p)$ given by

$$(3.1) \quad \mathbf{x}(s_i) = c_i(p) + s_i^0(s_i)(f(p) - c_i(p)) + r_i(p) \sum_{a \in \mathcal{A}_i} s_i^a e_a(p),$$

where $s_i^0(s_i) = \sqrt{1 - |s_i|^2}$, for all s_i in the open ball $B^{m_i}(\epsilon_i) \subset \mathbf{R}^{m_i}$, for some radius ϵ_i satisfying $0 < \epsilon_i < 1$. The components of s_i are denoted s_i^a , for each $a \in \mathcal{A}_i$, so $|s_i|^2 = 1 - \sum_{a \in \mathcal{A}_i} (s_i^a)^2$. The vectors $c_i(p)$, $f(p)$, and $e_a(p)$, for all $a \in \mathcal{A}_i$, are determined by $j_p^3(f)$.

Lemma 3. *For any $s_i \in B^{m_i}(\epsilon_i)$ in the parametrization (3.1), $j_{x_i(s_i)}^k(f)$ depends analytically algebraically on s_i and on $j_p^{k+3}(f)$, for any $k \geq 0$, where $x_i(s_i)$ denotes the point for which $f(x_i(s_i)) = \mathbf{x}(s_i)$.*

Proof. For some $\delta > 0$, there exists $y : B^{n-1-m_i}(\delta) \rightarrow Y \subset M$, an embedded submanifold through $y(0) = p$ transverse to the i^{th} curvature surface through each of its points. Let $c_i(y)$ be the center of the i^{th} curvature surface through $f(y)$. Let e_j , $j = 1, \dots, n-1$, be a smooth orthonormal frame field of principal vectors on a neighborhood of p . For each $y \in Y$,

$$(3.2) \quad f(x_i(s_i), y) = c_i(y) + s_i^0(s_i)(f(y) - c_i(y)) + r_i(y) \sum_{a \in \mathcal{A}_i} s_i^a e_a(y)$$

is a parametrization of a neighborhood of the i^{th} curvature surface through $f(y)$. Thus, for ϵ_i and δ sufficiently small, (x_i, y) is a parametrization of a neighborhood of p in M .

From (3.2) we see that the partial derivatives of f with respect to the s_i variables at (s_i, y) depend on $j_{(0,y)}^3(f)$ and analytically algebraically

on s_i , since all partial derivatives of $s_i^0(s_i)$ are analytic algebraic. Again from (3.2) we see that the partial derivatives of f with respect to the y variables at (s_i, y) depend analytically algebraically on s_i and on $j_{(0,y)}^1(c_i)$, $j_{(0,y)}^1(f)$, $j_{(0,y)}^1(r_i)$, and $j_{(0,y)}^1(e_a)$, for all $a \in \mathcal{A}_i$. Since $c_i(0, y)$, $f(0, y)$, $r_i(0, y)$, and the $e_a(0, y)$ are determined by $j_{(0,y)}^3(f)$, it follows that their 1-jets are determined by

$$(3.3) \quad j_{(0,y)}^1(j^3(f)) = j_{(0,y)}^4(f).$$

Taking higher derivatives of (3.2) in this way, we see that $j_{(x_i(s_i), y)}^k(f)$ depends analytically algebraically on s_i and on

$$(3.4) \quad j_p^k(j^3(f)) = j_p^{k+3}(f).$$

□

Theorem 4. *For any point $p \in M$, there exists an analytic algebraic parametrization of a neighborhood of $f(p)$ in $f(M) \subset \mathbf{R}^n$, where analytic algebraic means that the component functions are analytic algebraic. This collection of analytic algebraic parametrizations defines an analytic structure on M with respect to which f is analytic. In addition, it shows that any point $p \in M$ has an open neighborhood $U \subset M$ such that $f(U)$ is a semi-algebraic subset of \mathbf{R}^n .*

Proof. The idea is to iterate parametrizations along curvature surfaces, starting with the first. Choose a point $p \in M$. Setting $i = 1$ in equation (3.1) gives an analytic algebraic parametrization of a neighborhood of $f(p)$ of the first curvature surface through p . To simplify the following notation, we will write $f(s_1)$ in place of $f(x_1(s_1))$, and likewise $c_2(s_1)$, $r_2(s_1)$, and $e_b(s_1)$ without showing explicitly the composition with the map $x_1(s_1)$, etc.

For each s_1 , parametrize a neighborhood of the second curvature surface through $f(s_1)$ by

$$(3.5) \quad f(s_1, s_2) = c_2(s_1) + s_2^0(s_2)(f(s_1) - c_2(s_1)) + r_2(s_1) \sum_{b \in \mathcal{A}_2} s_2^b e_b(s_1)$$

where $c_2(s_1)$, $f(s_1)$, and $e_b(s_1)$, $b \in \mathcal{A}_2$, are determined by $j_{s_1}^3(f)$, which in turn depends analytically algebraically on s_1 and $j_p^3(j^3(f)) = j_p^6(f)$, by Lemma 3.

If $g > 2$, then one more step should make the iteration clear. For each $s_1, s_2 \in B_1(\epsilon_1) \times B_2(\epsilon_2)$, parametrize a neighborhood of the third curvature surface through $f(s_1, s_2)$ by

$$(3.6) \quad \begin{aligned} f(s_1, s_2, s_3) &= c_3(s_1, s_2) + s_3^0(s_3)(f(s_1, s_2) - c_3(s_1, s_2)) \\ &\quad + r_3(s_1, s_2) \sum_{c \in \mathcal{A}_3} s_3^c e_c(s_1, s_2). \end{aligned}$$

Now $c_3(s_1, s_2)$, $f(s_1, s_2)$, and $e_c(s_1, s_2)$ are determined by $j_{(s_1, s_2)}^3(f)$, which in turn depends analytically algebraically on s_2 and $j_{(s_1, 0)}^3(j^3(f)) = j_{(s_1, 0)}^6(f)$, which in turn depends analytically algebraically on s_1 and $j_p^3(j^6(f)) = j_p^9(f)$. Continuing in this way, we parametrize a neighborhood of the g^{th} curvature surface through $f(s_1, \dots, s_{g-1})$ by

$$(3.7) \quad \begin{aligned} f(s_1, \dots, s_g) &= c_g(s_1, \dots, s_{g-1}) \\ &+ s_g^0(s_g)(f(s_1, \dots, s_{g-1}) - c_g(s_1, \dots, s_{g-1})) \\ &+ r_g(s_1, \dots, s_{g-1}) \sum_{d \in \mathcal{A}_g} s_g^d e_d(s_1, \dots, s_{g-1}), \end{aligned}$$

which is analytic algebraic in $(s_1, \dots, s_g) \in B^{m_1}(\epsilon_1) \times \dots \times B^{m_g}(\epsilon_g)$ and depends on the finite set of constants determined by $j_p^{3g}(f)$. By a standard argument [17, p. 497]), $f(s_1, \dots, s_g)$ parametrizes a neighborhood of $p \in M$. Finally, since a finite product of open balls is a semi-algebraic subset of \mathbf{R}^{n-1} , its image under the analytic algebraic map (3.7) is a semi-algebraic subset of \mathbf{R}^n . \square

Corollary 5. *A connected proper Dupin hypersurface M in \mathbf{R}^n is an open subset of a connected component of the irreducible algebraic set $\overline{M}^{\text{zar}}$ of dimension $n - 1$.*

Proof. By the theorem, for any point $p \in M$, there is an open neighborhood $U \subset M$ of the point that is a semi-algebraic subset of \mathbf{R}^n . The result now follows from Lemma 1. \square

A slightly more general result holds that we shall apply to Dupin hypersurfaces.

Corollary 6. *If a connected analytic hypersurface $N \subset \mathbf{R}^n$ contains a connected proper Dupin hypersurface M , then N is an open subset of the connected component of an irreducible algebraic set that contains M .*

Proof. An open subset of M is open in N , so the result follows from Lemma 1. \square

4. THE FINITENESS CONDITION

A connected Dupin hypersurface M in \mathbf{R}^n has an open dense subset \mathcal{G} such that each connected component of \mathcal{G} is proper Dupin. In fact, \mathcal{G} is the set on which the multiplicities of the principal curvatures are locally constant [14]. Decompose \mathcal{G} into its at most countably many disjoint connected components $\mathcal{G}_1, \mathcal{G}_2, \mathcal{G}_3, \dots$. By Corollary 6, if the Dupin hypersurface M were an analytic submanifold of \mathbf{R}^n , then, since it contains the connected proper Dupin hypersurface \mathcal{G}_1 , it would be

contained in an irreducible algebraic set of dimension $n - 1$. Hence, our goal is to prove that M is an analytic hypersurface of \mathbf{R}^n .

Let \mathcal{G}^c denote the complement of \mathcal{G} in M . It is the set of points in M that do not have a proper Dupin neighborhood.

Definition 7. A connected Dupin hypersurface M of \mathbf{R}^n has the *local finiteness property* if there is a subset $S \subset \mathcal{G}^c$, closed in M , such that S disconnects M into only a finite number of connected components, and for each point $p \in \mathcal{G}^c$ not in S , there is an open neighborhood W of p in M such that $W \cap \mathcal{G}$ contains a finite number of connected open sets whose union is dense in W . We call S the set of *bad points* in \mathcal{G}^c .

Theorem 8. *Let M be a connected Dupin hypersurface in \mathbf{R}^n . If M has the local finiteness property, then it is an analytic submanifold of \mathbf{R}^n , and is therefore contained in a connected component of dimension $n - 1$ of an irreducible algebraic set.*

Proof. Let $\mathcal{G} \subset M$ be the open dense subset of M whose connected components are proper Dupin hypersurfaces in \mathbf{R}^n . Let $S \subset \mathcal{G}^c$ be the set of bad points in \mathcal{G}^c . By the local finiteness property, each point $p \in \mathcal{G}^c$ not in S has a neighborhood W , open in M , such that $W \cap \mathcal{G}$ contains a finite number of connected open sets U_1, \dots, U_s , whose union is dense in W . Note that \mathcal{G} dense in M implies that $W \subset \cup_1^s \overline{U}_i$, where \overline{U}_i is the topological closure of U_i in M . By Corollary 6, each U_i is contained in an irreducible algebraic set C_i . Then \overline{U}_i is a subset of C_i since C_i is closed. Hence, $W \subset \cup_1^s \overline{U}_i \subset \cup_1^s C_i$, which is a semi-algebraic subset of \mathbf{R}^n .

By Lemma 2, since W is a C^∞ -manifold, there is a connected open semi-algebraic subset U of $\cup_1^s C_i$ contained in W with $p \in U$. The intersection B of U with any open ball of \mathbf{R}^n centered at p is still an open subset of M and a semi-algebraic subset. Thus, we may assume B is so small that it is the graph of $h : D \rightarrow \mathbf{R}$ for some open set $D \subset \mathbf{R}^{n-1}$ by performing a linear change of coordinates (x^1, \dots, x^n) in \mathbf{R}^n if necessary. Since the projection $\pi : (x^1, \dots, x^n) \mapsto (x^1, \dots, x^{n-1})$, which is semi-algebraic, sends B to D , we see D is a semi-algebraic subset of \mathbf{R}^{n-1} . Thus, the map h is semi-algebraic, because its graph $\{(x, h(x)) : x \in D\} = B$ is a semi-algebraic subset of \mathbf{R}^n . Therefore, h is a Nash function and so it must be analytic algebraic, and the map $H : D \rightarrow B$, $H(x) = (x, h(x))$ is an analytic algebraic parametrization of the open neighborhood $B \subset M$ about p . Since $p \in \mathcal{G}^c \setminus S$ was arbitrary, and since every point of \mathcal{G} has a neighborhood with an analytic algebraic parametrization by Theorem 4, it follows that $M \setminus S$ is an analytic submanifold of \mathbf{R}^n . Since $M \setminus S$ has a finite number of connected

components, each of which contains an open subset that is a semi-algebraic subset of \mathbf{R}^n , it follows that $M \setminus S$ is contained in the union C of finitely many irreducible algebraic sets. Then M is contained in the topological closure of $M \setminus S$ which in turn must be contained in the closed set C .

Now let q be any point in S and consider M itself as an open neighborhood about q . Then M is a C^∞ manifold contained in the semi-algebraic set C . Apply the above argument to conclude that some open neighborhood of q in M is the image of an analytic algebraic parametrization. Hence, every point of M has an analytic parametrization, and M is an analytic hypersurface of \mathbf{R}^n . \square

Theorem 9. (a) *If M^{n-1} is a connected, compact taut hypersurface in \mathbf{R}^n that satisfies the local finiteness property, then M^{n-1} is an analytic submanifold and a connected component of an irreducible algebraic subset of \mathbf{R}^n .*

(b) *If M^m is a connected, compact taut submanifold of codimension greater than one in \mathbf{R}^n such that the tube M_ϵ over M , which is Dupin, satisfies the local finiteness property, then M is an analytic submanifold and a connected component of an irreducible algebraic subset of \mathbf{R}^n .*

Proof. (a) Since a taut hypersurface must be Dupin [11], this follows immediately from Theorem 8.

(b) Let M be an embedded taut connected, compact submanifold in \mathbf{R}^n and let M_ϵ be a tube over M of sufficiently small radius that M_ϵ is an embedded hypersurface in \mathbf{R}^n . Then M_ϵ is a Dupin hypersurface [11]. Thus $M_\epsilon \subset \mathbf{R}^n$ is semi-algebraic by Theorem 8, since M_ϵ satisfies the local finiteness property. Then M itself is algebraic, since it is the image of the semi-algebraic focal map $F_\epsilon : M_\epsilon \rightarrow M \subset \mathbf{R}^n$ given by $F_\epsilon(x) = x - \epsilon\xi$, where ξ is the outward field of unit normals to the tube M_ϵ . \square

5. ENDS AND ALEXANDER COHOMOLOGY

An *end* of a noncompact manifold X is an equivalence class of sequences of connected open neighborhoods X, U_1, U_2, \dots , where $U_{n+1} \subset U_n$, such that the intersection of the closures of these sets is the empty set, subject to the equivalence relation $(X, U_1, U_2, \dots) \sim (X, W_1, W_2, \dots)$ if for each U_i there is a j with $U_i \subset W_j$, and for each W_k there is an m such that $W_k \subset U_m$ [6].

Let S be a closed subset of a manifold M . The k -th *Alexander cohomology group* is defined to be the direct limit $\overline{H}^k(S) := \lim_{\rightarrow} H^k(V)$, where $H^k(V)$ is the usual k -th singular cohomology group of open $V \supset S$.

For any topological space X , a function f from X to \mathbf{Z}_2 is said to be *locally constant* if there is an open covering \mathcal{U} of X such that f is constant on each element of \mathcal{U} . The following theorem can be found in [15, p. 309].

Theorem 10. $\overline{H}^0(S)$ is the \mathbf{Z}_2 -module of locally constant functions from S to \mathbf{Z}_2 . In particular, if all the topological connected components of S are open in S , then the rank of $\overline{H}^0(S)$ is identified with the cardinality of the set of connected components of S .

We only sketch very briefly how to prove the following corollaries of the preceding theorem.

Corollary 11. Let M be a compact simply connected manifold. Let $S \subset M$ be a closed subset for which $M \setminus S$ has only finitely many connected components. Suppose all the connected components of S are open (whose cardinality is necessarily finite) in S . Then the number of ends of $M \setminus S$ is finite.

That M is simply connected so that $H^1(M) = 0$ is employed for the short exactness of the H^0 -block of a Mayer-Vietoris sequence obtained by the covering of M by $M \setminus S$ and $U_j, j = 1, 2, \dots$, a sequence of shrinking neighborhoods of S corresponding to the ends of $M \setminus S$. This gives a counting of the rank of $H^0(U_j)$, which would diverge to infinity if the number of ends of $M \setminus S$ was infinite. But then the preceding theorem would yield a contradiction when one takes the direct limit over U_j .

Corollary 12. Let M be a manifold of finitely many connected components and $S \subset M$ be closed. If $M \setminus S$ has finitely many ends, then S has finitely many connected components each of which is open in S .

For the proof, one chases the diagram of the Mayer-Vietoris sequence up to $H^1(M)$ to show the number of connected components of U_j is bounded, and so eventually it stabilizes to a number m . From this it follows that $\overline{H}^0(S)$ is of rank m by taking direct limit over U_j , and $U_j \cap S$ for large j constitute the m open connected components of S . We call S the *end set* of $M \setminus S$.

6. APPLICATION TO COMPACT TAUT SUBMANIFOLDS

Let M be a compact taut hypersurface in S^n . Consider the normal exponential map $E : M \times (-\pi, \pi) \rightarrow S^n$, where

$$E : (p, t) \mapsto \cos(t)p + \sin(t)\mathbf{n},$$

with \mathbf{n} the chosen unit normal field of M . Here, E is smooth at points where $t = -\pi, \pi$.

A point $q = E(p, t)$ is called a *focal point of multiplicity $m > 0$ of M at p* if the nullity of the derivative E_* is equal to m at (p, t) . The set of all focal points is the *focal set \mathcal{F}* of M . The focal points at p are antipodally symmetric on the circle $E(p, t)$ with each principal curvature of the form $\cot(t)$ for some $t \neq 0$. Let \mathcal{Z} be the complement of \mathcal{F} in S^n .

Lemma 13. *\mathcal{Z} is connected in S^n .*

Proof. By Federer's version of Sard's theorem [5, p. 316], the image of the critical points of a given smooth function $f : \mathbf{R}^t \rightarrow \mathbf{R}^s$, at which the rank of the derivative is less than or equal to ν , is of \mathcal{H}^ν -measure 0, where \mathcal{H}^ν denotes the Hausdorff ν -dimensional measure.

Label the principal curvature functions by $\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_{n-1}$. It is known that λ_j are continuous [12]. Let $\cot(t_j) := \lambda_j$, $0 < t_j < \pi$. We know that the focal maps

$$(6.1) \quad f_j(p) = \cos(t_j)p + \sin(t_j)\mathbf{n}$$

are continuous and are smooth on a dense open set.

For each i , let O_i be the open subset of M on which λ_i has multiplicity 1. (O_i could be empty.) Then O_i consists of countably many open components O_{ij} , $j = 1, 2, \dots$, such that the restriction of f_i to (O_{ij}) is an embedded submanifold of dimension $n - 2$. This follows from the fact that λ_i is constant on its lines of curvature on each O_{ij} by the Dupin condition.

Let Z_i be the complement of O_i in M . (Z_i could be empty.) At each point p of Z_i , the principal curvature $\cot(t_i)$ must have multiplicity at least 2, and so the normal exponential map E has rank $\leq n - 2$ at the point (p, t_i) . Thus the focal point $f_i(p)$ lies in the singular value set K of points for which the derivative of E has rank $\leq n - 2$.

We conclude that the entire focal set \mathcal{F} is composed of the countably many embedded submanifolds $f_i(O_{ij})$ of dimension $n - 2$, their antipodal sets and the set K which has Hausdorff $(n - 2)$ -measure zero by Federer's theorem quoted above. Therefore, the Hausdorff $(n - 1)$ -measure of the whole focal set \mathcal{F} is zero, which implies that the complement \mathcal{Z} of \mathcal{F} is connected [13, p. 269]. \square

Away from \mathcal{F} , the map E is a local diffeomorphism. For each $0 \leq m \leq n - 1$, we let W_m be the set of points (p, t) in $E^{-1}(\mathcal{Z})$ for which the spherical distance function d_q , where $q = E(p, t)$, has index m at p . Then the tautness of M implies that $E : W_m \rightarrow \mathcal{Z}$ is a degree b_m (regular) covering map, where b_m is the m -th Betti number. Therefore,

by the connectedness of \mathcal{Z} , the set W_m decomposes into finitely many (connected) covering sheets $W_{m1}, W_{m2}, \dots, W_{ms_m}$ onto \mathcal{Z} , where $s_m \leq b_m$. W_m will be composed of connected components either in $M \times (0, \pi)$ or $M \times (-\pi, 0)$. We denote by W_{mj}^+ those W_{mj} contained in $M \times (0, \pi)$. We set $W_m^+ := \cup_j W_{mj}^+$.

Lemma 14. *All the connected components of \mathcal{F} are open in \mathcal{F} . In particular, the number of ends of \mathcal{Z} is finite.*

Proof. Since each $f_j(M)$, $1 \leq j \leq n-1$, defined in (6.1) is compact and path-connected in S^n , we can group them and the sets antipodal to them into classes where the union of those $f_j(M)$ in each class is path-connected whereas the unions from different classes are disjoint. Call these disjoint unions X_1, \dots, X_r , each of which, being a finite union of compact sets, is closed in S^n and path-connected. Hence by the Urysohn separation lemma, there are disjoint open sets O_1, \dots, O_r that contain X_1, \dots, X_r , respectively. This means that each (topological) component, now being just the path-connected components, are open in the relative topology. The conclusion follows by Corollary 11. \square

Corollary 15. *Each W_{mj}^+ has a finite number of ends.*

Proof. This follows since $E : W_{mj}^+ \rightarrow \mathcal{Z}$ is a proper map because it is a covering map of finite degree and \mathcal{Z} has a finite number of ends. \square

Let $pr : M \times (-\pi, \pi) \rightarrow M$ be the projection. Since pr is an open map, the sets

$$(6.2) \quad U_{mj}^+ := pr(W_{mj}^+)$$

are open and connected in M . We also set

$$(6.3) \quad U_m^+ := \cup_j U_{mj}^+ = pr(W_m^+).$$

It is clear that W_m^- and U_m^- can be similarly defined on $M \times (-\pi, 0)$.

Definition 16. We define $(U_m^*)^+$ to be the collection of all x for which there exists a $t > 0$ such that (x, t) is a regular point of the normal exponential map E , and the spherical distance function d_y , where $y = E(x, t)$, has index m at x .

Note that $U_m^+ \subset (U_m^*)^+$ by definition. Further, any point p in the complement $(U_m^*)^+ \setminus U_m^+$ satisfies the condition that every $q = E(p, t)$, $t > 0$, on the normal exponential circle, such that d_q has a non-degenerate critical point of index m at p , is a focal point of some other point in M .

Lemma 17. *$(U_m^*)^+$ is open in M .*

Proof. This follows from the property that E is a local diffeomorphism around (x, t) , $t > 0$, so that $E(x, t)$ is nonfocal along the normal exponential circle. Hence, for a point (x', t') near (x, t) , the point $E(x', t')$ is also nonfocal along the respective normal exponential circle. Now, d_y has index m at the nondegenerate critical point x . When x' is sufficiently close to x , the function $d_{y'}$, $y' = E(x', t')$, is a slight perturbation of d_y . Since x' is a nondegenerate critical point of $d_{y'}$ and since nondegenerate critical points are locally structurally stable, $d_{y'}$ must also have index m at x' , so that $x' \in (U_m^*)^+$. \square

For (p, t_1) and (p, t_2) in $M \times (0, \pi)$, we say (p, t_1) is equivalent to (p, t_2) , denoted $(p, t_1) \sim (p, t_2)$, if the distance functions d_{q_1} , for $q_1 = E(p, t_1)$, and d_{q_2} , for $q_2 = E(p, t_2)$, have nondegenerate critical points of the same index m at p . We then let L_{mj} be the (trivial) line bundle (6.4)

$$L_{mj} := \{(p, t) \in M \times (0, \pi) : (p, t) \sim (p, t_0) \text{ for some } (p, t_0) \in W_{mj}\}$$

over U_{mj}^+ .

Lemma 18. $L_{mj} \setminus W_{mj}^+$ is of Hausdorff codimension at least 2 in L_{mj} . In particular, L_{mj} and U_{mj}^+ are of finite number of ends.

Proof. By the openness of W_{mj}^+ , we know $L_{mj} \setminus W_{mj}^+$ is closed in L_{mj} . We next show that $L_{mj} \setminus W_{mj}^+$ is of Hausdorff codimension at least 2. Consider the restriction of the map E on $L_{mj} \setminus W_{mj}^+$ given by

$$f := (p, t) \in L_{mj} \setminus W_{mj}^+ \mapsto E(p, t) \in \mathcal{F}.$$

Note that f is a finite-to-one map. This is because for any $z \in \mathcal{F}$, the height function ℓ_z is a perfect Morse-Bott function [9], and each p , for which some point of the form (p, t) is in $f^{-1}(z)$, is a nondegenerate critical point of index m of ℓ_z on the taut hypersurface M . Such a nondegenerate critical point is a critical submanifold. Hence the total number of such points is no more than b_m , the m -th Betti number of M .

The image of f is a closed subset of \mathcal{F} of Hausdorff codimension at least 2 by Lemma 13. E is a local diffeomorphism at $(p, t) \in L_{mj}$ when it is restricted to L_{mj} . Hence, there is a neighborhood $Y_{(p,t)} \subset L_{mj}$ around each $(p, t) \in L_{mj} \setminus W_{mj}^+$ such that f restricted to $Y_{(p,t)} \cap (L_{mj} \setminus W_{mj}^+)$ is a homeomorphism into \mathcal{F} . It follows that the Hausdorff $(n-2)$ -measure of $L_{mj} \setminus W_{mj}^+$ is at most b_m times that of \mathcal{F} , which is null in the ambient sphere S^n . So, $L_{mj} \setminus W_{mj}^+$ is of Hausdorff codimension at least 2 in L_{mj} . In particular, $L_{mj} \setminus W_{mj}^+$ does not disconnect L_{mj} .

We now apply Corollary 12 with $S = L_{mj} \setminus W_{mj}^+$, $M = L_{mj}$ and $X = M \setminus S = W_{mj}^+$. Since X has a finite number of ends, it follows that S has finitely many components all of which are open in S . Now, suppose M has infinitely many ends. Then there is a decreasing sequence of open sets X_1, X_2, \dots , in X such that $X \setminus X_j$ is compact, $\bigcap_j \overline{X_j} = \emptyset$ and the number of unbounded connected components of X_j increasingly diverges to infinity. As S has finitely many components S_1, \dots, S_t , all of which are of Hausdorff codimension at least 2, S_1, \dots, S_t cannot disconnect the connected components of X_j . We see $X_j \setminus S$ form a decreasing sequence whose disconnected components diverge to infinity, so that $W_{mj}^+ = M \setminus S$ will have infinitely many ends. This contradiction establishes that L_{mj} has a finite number of ends. Since L_{mj} is a trivial line bundle over U_{mj}^+ , so that $L_{mj} \simeq U_{mj}^+ \times \mathbf{R}$, it follows that U_{mj}^+ has a finite number of ends. \square

Corollary 19. W_{mj}^+ is disjoint from W_{ml}^+ if and only if U_{mj}^+ is disjoint from U_{ml}^+ . In particular, U_m^+ has finitely many ends.

Proof. The backward direction is clear. To prove the forward direction, suppose $p \in U_{mj}^+ \cap U_{ml}^+$. Let $X := U_{mj}^+ \cup U_{ml}^+$ and let $Y := W_{mj}^+ \cup W_{ml}^+$. Since X is open and connected, we can form the (trivial) line bundle L over X , where L consists of $(p, t), p \in X$, such that the distance function d_q , for $q = E(p, t)$, has a nondegenerate critical point of index m at p . Then $L = L_{mj} \cup L_{ml}$ and $Y \subset L$ by construction. However, the analysis in Lemma 18 shows that $L \setminus Y$ is of Hausdorff codimension at least 2; therefore, Y is connected, and so W_{mj}^+ and W_{ml}^+ cannot be disjoint. Now that U_m^+ is the finite disjoint union of all U_{mj}^+ , each of which has finitely many ends, it follows that the same is true for U_m^+ . \square

Corollary 20. U_m^+ is dense in $(U_m^*)^+$. In particular, $(U_m^*)^+$ has a finite number of connected components.

Proof. Suppose that U_m^+ is not dense in $(U_m^*)^+$. Then there is an open set $X \subset (U_m^*)^+$ that is disjoint from U_m^+ . Similar to Corollary 19, let us introduce the line bundle L over X , which consists of all points $(p, t), t > 0$, where $p \in X$ and d_q , for $q = E(p, t)$, has a nondegenerate critical point of index m at p .

Every point $(p, t) \in L$ is mapped to \mathcal{F} via the map E , since $p \in (U_m^*)^+ \setminus U_m^+$. As we see in Lemma 18, the map f of Lemma 18 on L is finite-to-one and regular at every point of L . Thus, the image of f contains an open set of dimension $n = \dim L$. This contradicts the fact that the Hausdorff codimension of \mathcal{F} is at least two. Thus, U_m^+ is dense in $(U_m^*)^+$.

In particular, $(U_m^*)^+$ also has a finite number of connected components, because any of its components will contain at least one component of U_m^+ . \square

Recall that we say a point p is a good point in the taut hypersurface M if the multiplicities of the principal curvatures are locally constant around p . We denote the set of good points by \mathcal{G} . We know \mathcal{G} is open and dense in M .

Our convention is that we label the principal curvature functions by $\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_{n-1}$. When we say (m_1, m_2, \dots, m_g) is a given sequence of principal multiplicities, we mean that

$$\lambda_1 = \dots = \lambda_{m_1}, \quad \lambda_{m_1+1} = \dots = \lambda_{m_1+m_2}, \dots,$$

so that m_i is the multiplicity of the i^{th} largest distinct principal curvature.

Lemma 21. *There is a dense open subset of \mathcal{G} such that for any p in the subset, there is a point $q \in \mathcal{Z}$ between any two focal points on the normal exponential circle $E(p, t), t > 0$.*

Proof. Let X be a connected component of \mathcal{G} assuming multiplicities (m_1, m_2, \dots, m_μ) . Let $\sigma_s = m_1 + \dots + m_s$, for $1 \leq s \leq \mu$. Then $X \subset (U_{\sigma_s}^*)^+$. Then Corollary 20 implies that $X \cap U_{\sigma_s}^+$ is dense and open in X . \square

Definition 22. We let \mathcal{G}° be the largest dense open subset of \mathcal{G} over which Lemma 21 is true.

Lemma 23. *Let g be the maximum number of distinct principal curvatures on M . Let $\mathcal{M} := (m_1, \dots, m_g)$ be a given maximal sequence of multiplicities. Let $\mathcal{O}_{\mathcal{M}} \subset \mathcal{G}^\circ$ be the (open) subset of \mathcal{G}° attaining these multiplicities. Let $\sigma_j = m_1 + \dots + m_j$, for $1 \leq j \leq g$. Then $\mathcal{O}_{\mathcal{M}}$ is the intersection of all $U_{\sigma_j}^+$.*

Proof. The intersection consists of all points p such that there is some $0 < t_j < \pi$ for which p is of index σ_j with respect to the distance function d_q , with $q = E(p, t_j)$, for each j . So, p must have g principal curvatures with multiplicities m_1, m_2, \dots, m_g . The maximality of g implies that m_j cannot be broken further into smaller multiplicities. Moreover, since $p \in U_{\sigma_j}^+$, there is a t for which $E(p, t)$ between the two appropriate focal points is in \mathcal{Z} . We obtain $p \in \mathcal{G}^\circ$. So, $\cap U_{\sigma_j}^+ \subset \mathcal{O}_{\mathcal{M}}$.

Conversely, since $\mathcal{O}_{\mathcal{M}} \subset \mathcal{G}^\circ$, it follows by the definition of $U_{\sigma_j}^+$ that $\mathcal{O}_{\mathcal{M}} \subset \cap U_{\sigma_j}^+$. \square

We now proceed to handle the case of a taut submanifold of dimension 3 or 4. First we need the following lemma in homology that will be needed in our proof.

Lemma 24. *Let $B_1 \subset B_2$ be two closed disks. Then the k^{th} new topology of the taut submanifold M added between $B_1 \cap M$ and $B_2 \cap M$ is the relative homology*

$$H_k(B_2 \cap M, B_1 \cap M).$$

Proof. This follows from the exact sequence

$$\begin{aligned} \rightarrow H_k(B_1 \cap M) &\xrightarrow{i} H_k(B_2 \cap M) \rightarrow H_k(B_2 \cap M, B_1 \cap M) \\ &\xrightarrow{j} H_{k-1}(B_1 \cap M) \xrightarrow{i} H_{k-1}(B_2 \cap M) \rightarrow \end{aligned}$$

and the fact that i is injective by the injectivity property of tautness, so that j is surjective. It follows that

$$H_k(B_2 \cap M) = H_k(B_1 \cap M) \oplus H_k(B_2 \cap M, B_1 \cap M),$$

and hence the conclusion. □

Corollary 25. *If $B_1 \subset B_2 \subset B_3$ are three closed disks, then*

$$H_k(B_3 \cap M, B_1 \cap M) = H_k(B_3 \cap M, B_2 \cap M) \oplus H_k(B_2 \cap M, B_1 \cap M).$$

Thus, $H_k(B_3 \cap M, B_1 \cap M)$ is surjective to both $H_k(B_3 \cap M, B_2 \cap M)$ and $H_k(B_2 \cap M, B_1 \cap M)$.

Proof. Given three abelian groups $A \rightarrow B \rightarrow C$, where each arrow is an embedding, then $C/B = (C/A)/(B/A)$. □

Lemma 26. *Suppose $\dim M = 4$.*

(a) *If the maximum number of principal curvatures is ≥ 3 , then multiplicities $(1, 3)$, $(3, 1)$ and $(2, 2)$ cannot exist on open sets.*

(b) *If the maximum number of principal curvatures is 4, then the points with multiplicities $(1, 1, 2)$, $(1, 2, 1)$ and $(2, 1, 1)$, at which the number of principal curvatures is not locally constant, cannot be approached by a sequence coming from an open set of points of the same multiplicities.*

Proof. (a) Suppose the multiplicities are $(1, 3)$ on an open set O . Let $x \in O$ and let p be a boundary point of O . Let $c(t)$ be a smooth curve with $c(0) = x$ and $c(1) = p$. We can assume that $c(t) \in O$ for $0 \leq t < 1$. Since p is a boundary point of O , there must be a sequence of points with multiplicities $(1, 1, 2)$, $(1, 2, 1)$ or $(1, 1, 1, 1)$ that converges to p . The multiplicities must remain $(1, 3)$ at p ; otherwise, the list of multiplicities would drop to the single multiplicity (4) , and this is impossible, because a taut hypersurface with a single umbilic point must be a totally umbilic sphere. We will handle the case where a

sequence of points with multiplicities $(1, 1, 2)$ approaches p . The other cases are very similar.

At each point $c(t)$, $0 \leq t < 1$, the curvature surface $S(t)$ corresponding to the principal curvature λ of multiplicity 3 is a 3-dimensional metric sphere, which converges to the 3-dimensional curvature surface, a 3-sphere, corresponding to λ at p , as t approaches 1. On the other hand, consider a sequence of points $\{y_i\}$ where the multiplicities are $(1, 1, 2)$ that approaches p . For each y_i , the 2-dimensional curvature surface C_i through y_i corresponding to the principal curvature of multiplicity 2 is a topset for the spherical distance function centered at the corresponding focal point. Thus, by tautness, C_i represents a nontrivial 2-dimensional homology class in M . As y_i approaches p , these C_i approach a 2-cycle C in the curvature surface $S(1)$ that is nontrivial in the 2-dimensional homology of $S(1)$. This is a contradiction, since $S(1)$ is a 3-sphere and has trivial 2-dimensional homology. A similar proof shows that multiplicities $(3, 1)$ cannot exist on an open set.

Next suppose that the multiplicities are $(2, 2)$ on an open set O . As in the argument above, let $x \in O$ and let p be a boundary point of O . Let $c(t)$ be a smooth curve with $c(0) = x$, $c(1) = p$ and $c(t) \in O$ for $0 \leq t < 1$. Then the multiplicities must be $(2, 2)$ at p . Since p is a boundary point of O , there must be a sequence of points with multiplicities $(1, 1, 2)$, $(2, 1, 1)$ or $(1, 1, 1, 1)$ that converges to p . We will handle the case where the multiplicities are $(1, 1, 2)$, and the others are handled similarly. Then as in the argument above, at each point $c(t)$, $0 \leq t < 1$, the curvature surface $S(t)$ corresponding to the first principal curvature λ of multiplicity 2 is a 2-dimensional metric sphere, which converges to the curvature surface, a 2-sphere, corresponding to λ at p . On the other hand, there is a sequence $\{y_i\}$ approaching p such that the multiplicities are $(1, 1, 2)$ at y_i . Again, the topset property as above gives a contradiction.

(b) In the case of multiplicities $(1, 1, 2)$ or $(2, 1, 1)$, the same type of argument takes care of this statement, since one can produce a point p with the given multiplicities that is also a limit of a sequence of points with multiplicities $(1, 1, 1, 1)$.

In the case of multiplicities $(1, 2, 1)$, we need to modify the argument slightly. As above, the nondegenerate critical manifold at p corresponding to the principal curvature of multiplicity two is a metric 2-sphere S , and we can also approach p by a sequence of points with multiplicities $(1, 1, 1, 1)$. However, in this case, the 1-dimensional circles approaching p corresponding to the second and third multiplicities are not topsets. We can see that they still contribute in a nontrivial way to homology by the following argument.

At the point p , the multiplicities are $(1, 2, 1)$, and p is a limit point of the open connected set O on which the multiplicities are $(1, 2, 1)$. Let q be the second focal point of M at p corresponding to the principal curvature of multiplicity two. As above, we can also approach p by a sequence of points in the open set U with multiplicities $(1, 1, 1, 1)$. Thus near p , we can find points $x \in O$ and $y \in U$, with corresponding second focal points u and v near q such that the height functions $\ell_u(x) = a$, $\ell_v(y) = b$, and positive numbers ϵ and δ such that $M_{a-\epsilon}(\ell_u) \subset M_{b-\delta}^-(\ell_v) \subset M_b(\ell_v)$, and $M_a(\ell_u) \subset M_{b+\delta}^-(\ell_v) \subset M_{a+\epsilon}(\ell_u)$. Furthermore, using a genericity argument, we can assume that the points x and y are chosen so that the critical submanifolds of the corresponding height functions ℓ_u and ℓ_v are at distinct levels, and we may choose ϵ and δ sufficiently small so that a (respectively b) is the only critical value between $a - \epsilon$ and $a + \epsilon$ (respectively, between $b - \delta$ and $b + \delta$). Lemma 24 says that the new k^{th} homology between the levels $a - \epsilon$ and $a + \epsilon$ of ℓ_u is

$$(6.5) \quad H_k(M_{a+\epsilon}(\ell_u), M_{a-\epsilon}(\ell_u)).$$

Corollary 25 says that the group in equation (6.5) is surjective to

$$(6.6) \quad H_k(M_{a+\epsilon}(\ell_u), M_{b-\delta}(\ell_v)),$$

where in Lemma 24, we take

$$B_1 \cap M = M_{a-\epsilon}(\ell_u), B_2 \cap M = M_{b-\delta}(\ell_v), B_3 \cap M = M_{a+\epsilon}(\ell_u).$$

The same lemma says that the group in equation (6.6) is surjective to

$$(6.7) \quad H_k(M_{b+\delta}(\ell_v), M_{b-\delta}(\ell_v)),$$

where

$$B_1 \cap M = M_{b-\delta}(\ell_v), B_2 \cap M = M_{b+\delta}(\ell_v), B_3 \cap M = M_{a+\epsilon}(\ell_u).$$

It follows from these considerations that the group in equation (6.5) is surjective to the group in equation (6.7). However, by Morse-Bott critical point theory [4, p. 239], we have

$$(6.8) \quad H_k(M_{a+\epsilon}(\ell_u), M_{a-\epsilon}(\ell_u)) = H_{k-\mu}(W),$$

where W is the critical manifold of ℓ_u at x and μ is the index at x . Similarly, we have

$$(6.9) \quad H_k(M_{b+\delta}(\ell_v), M_{b-\delta}(\ell_v)) = H_{k-\nu}(V),$$

where V is the critical submanifold of ℓ_v at y and ν is the index at y .

Now the critical submanifold W at x is a 2-sphere of index $\mu = 1$, whereas the critical submanifold V at y is a circle of index $\nu = 1$. Using $k = 2$ in equations (6.8) and (6.9), we see that $0 = H_1(W, \mathbf{Z}_2)$ is surjective to $H_1(V, \mathbf{Z}_2) = \mathbf{Z}_2$. This is a contradiction. \square

Theorem 27. *Let M be a compact taut hypersurface in S^n that is not a hypersphere. If $\dim M = 3$, or 4, then M is algebraic.*

Proof. Assume $\dim M = 4$ and the maximum number of multiplicities is 4. By Lemma 26, multiplicities $(1, 3)$, $(3, 1)$ and $(2, 2)$ cannot exist on open sets. Meanwhile, the set of points with multiplicities $(1, 1, 1, 1)$ is open. Since by Lemma 26, a point with multiplicities $(1, 1, 2)$ (or $(1, 2, 1)$ or $(2, 1, 1)$) at which the number of principal curvatures is not locally constant cannot be approached by a sequence coming from an open set of points of the same multiplicities, we see that such points must be entirely surrounded by points with multiplicities $(1, 1, 1, 1)$. As a result, an open set of points with multiplicities $(1, 1, 2)$ will approach boundary points with multiplicities either $(1, 3)$ or $(2, 2)$.

The set \mathcal{G} of good points are those with multiplicities $(1, 1, 1, 1)$ and the points with multiplicities $(1, 1, 2)$, $(1, 2, 1)$, or $(2, 1, 1)$ that exist on open sets. \mathcal{G} is open and dense in M . We let S be the subset of \mathcal{G}^c consisting of points of multiplicities $(1, 3)$, $(3, 1)$ or $(2, 2)$. We wish to establish that the local finiteness property is true.

Firstly, S is closed in M . This is because any converging sequence of points of the indicated multiplicities must maintain the same type of multiplicities.

We next show that $M \setminus S$ has finitely many connected components. It comes down to showing that $A := (U_1^*)^+$ (respectively, $B := (U_2^*)^+$ or $C := (U_3^*)^+$), with points of multiplicities $(1, 3)$ (respectively, $(2, 2)$ or $(3, 1)$) removed, has only finitely many connected components; for then the union of the three resulting sets is exactly $M \setminus S$, which, being a union, must have finitely many connected components. However, as before, this follows from the Mayer-Vietoris sequence applied to the open covers A and $B \cup C$ of M , etc. Note that A is composed of points with multiplicities $(1, 1, 1, 1)$, $(1, 1, 2)$, $(1, 2, 1)$ or $(1, 3)$, B with multiplicities $(1, 1, 1, 1)$, $(1, 1, 2)$, $(2, 1, 1)$ or $(2, 2)$, and C with multiplicities $(1, 1, 1, 1)$, $(1, 2, 1)$, $(2, 1, 1)$ or $(3, 1)$. Hence, $A \cap (B \cup C)$ is exactly A with points of multiplicities $(1, 3)$ removed.

Lastly, we verify that each point in $\mathcal{G}^c \setminus S$ has a open neighborhood W in M such that $W \cap \mathcal{G}$ contains finitely many connected open sets whose union is dense in W .

As mentioned earlier, $\mathcal{G}^c \setminus S$ is completely surrounded by points of multiplicities $(1, 1, 1, 1)$. For each point $p \in \mathcal{G}^c \setminus S$ of multiplicities $(1, 1, 2)$, there is a small neighborhood of it which contains no points of multiplicities $(1, 2, 1)$ or $(2, 1, 1)$, etc. In other words, the sets

T_1, T_2, T_3 of points of multiplicities $(1, 1, 2), (1, 2, 1), (2, 1, 1)$, respectively, are contained in disjoint open sets O_1, O_2, O_3 , respectively, where $O_i \setminus T_i, 1 \leq i \leq 3$, consists of only points of multiplicities $(1, 1, 1, 1)$.

Let $X \subset (U_3)^+$ be the subset of points of multiplicities $(1, 1, 1, 1)$. X is dense in the set of points of multiplicities $(1, 1, 1, 1)$ by Lemmas 21 and 23. It follows that T_1 is contained in the end sets of the finitely many end components E_1, \dots, E_s of U_3^+ on which the multiplicities remain $(1, 1, 1, 1)$. Let W be the union of O_1 above and E_1, \dots, E_s . (O_1 is the union of neighborhoods of points of multiplicities $(1, 1, 2)$. We make sure each of these neighborhoods is so small that its intersection with U_3^+ is contained in the end components E_1, \dots, E_s .) Then $W \cap \mathcal{G}$ consists of only points of multiplicities $(1, 1, 1, 1)$, and moreover contains open sets E_1, \dots, E_s whose union is dense in W .

Similarly, the same conclusion is true for points of multiplicities $(2, 1, 1)$ and $(1, 2, 1)$ in \mathcal{G}^c with U_3^+ replaced by U_1^+ and U_2^+ , respectively. Hence, M is algebraic.

The case $\dim M = 3$ and $\dim M = 4$ when the maximal number of multiplicities is 3 follows from the same procedure. For the latter case, \mathcal{G}^c is the set of points with multiplicities $(1, 3), (3, 1)$ or $(2, 2)$, which coincides with S , so that the set $\mathcal{G}^c \setminus S = \emptyset$, and the local finiteness condition is automatically satisfied on $\mathcal{G}^c \setminus S$. Similarly for the former case, we have $\mathcal{G}^c = S$, which is the set of points with multiplicities $(1, 2)$ or $(2, 1)$. \square

By considering a tube M_ϵ with a small ϵ over a compact taut submanifold M , the method employed in the preceding theorem gives the theorem below in dimensions 3 and 4.

Banchoff [1] showed that a taut compact 1-dimensional submanifold of S^n must be a metric circle in S^n , which is certainly algebraic. In the same paper, he also showed that if M is a taut compact 2-dimensional surface substantially embedded in S^n , then M is a metric 2-sphere, a cyclide of Dupin in S^3 , or a spherical Veronese surface $V \subset S^4$. All of these surfaces are algebraic. Thus, we have the following result.

Theorem 28. *Let M be a compact taut m -dimensional submanifold in $S^n \subset \mathbf{R}^{n+1}$. If $m \leq 4$, then M is algebraic.*
