1. Overview

We will prove consistency and independence results. These are theorems which assert that within some given axiomatic system, some given proposition cannot be disproven or can be neither proven nor disproven.

Example: the parallel postulate in Euclidean geometry states:

Given a line and a point not on the line, only one line can be drawn through the point parallel to the line.

This statement is independent of the other four axioms:

1. A straight line can be drawn between any two points.
2. A finite line can be extended infinitely in both directions.
3. A circle can be drawn with any center and any radius.
4. All right angles are equal to each other.

How do we know this? The parallel postulate is consistent with the other four axioms because all five statements hold in the standard Euclidean plane. Its negation is consistent with the other four axioms because the sphere model ("point" is a point on the sphere, "line" is a great circle) satisfies the first four Euclidean axioms, but does not satisfy the parallel postulate. Thus, the parallel postulate is independent of the other axioms. (Another model where the parallel postulate fails is the Poincaré disk.)

Do the sphere and disk models really satisfy the first four Euclidean axioms? This is not perfectly clear because of the informal manner in which we stated the axioms. There seem to be some questions of interpretation, especially in the case of the sphere model. This illustrates the need to have a formal language in which our axioms can in principle be rigorously expressed.

Peano arithmetic is a good example of a rigorous, formal axiomatic system. We have an infinite list of variables $x, y, \ldots$; a constant symbol $0$; symbols for addition, multiplication, and successor $(+, \cdot, ')$; and parentheses. A term is any grammatical expression built up from these components. An atomic formula is a statement of the form $t_1 = t_2$ where $t_1$ and $t_2$ are terms. A formula is any statement built up from atomic
formulas using the logical symbols $\rightarrow$ (implies), $\neg$ (not), and $\forall$ (for all). (All of the other logical symbols can be defined in terms of these.)

The axioms of Peano arithmetic (PA) consist of the logical axioms:

\[
\begin{align*}
\phi & \rightarrow (\psi \rightarrow \phi) \\
[\phi \rightarrow (\psi \rightarrow \omega)] & \rightarrow [(\phi \rightarrow \psi) \rightarrow (\phi \rightarrow \omega)] \\
(\neg \psi \rightarrow \neg \phi) & \rightarrow [(-\psi \rightarrow \phi) \rightarrow \psi] \\
(\forall x)\phi(x) & \rightarrow \phi(t) \\
(\forall x)(\phi \rightarrow \psi) & \rightarrow [\phi \rightarrow (\forall x)\psi]
\end{align*}
\]

and the non-logical axioms:

\[
\begin{align*}
(x = y) & \rightarrow [(x = z) \rightarrow (y = z)] \\
(x = y) & \rightarrow x' = y' \\
(0 = x') & \\
(x' = y') & \rightarrow (x = y) \\
x + 0 & = x \\
x + y' & = (x + y)' \\
x \cdot 0 & = 0 \\
x \cdot (y') & = (x \cdot y) + x \\
\phi(0) & \rightarrow [(\forall x)(\phi(x) \rightarrow \phi(x')) \rightarrow (\forall x)\phi(x)].
\end{align*}
\]

These axioms are presented schematically, meaning that $\phi$, $\psi$, and $\omega$ stand for any formulas, $x$, $y$, and $z$ can be replaced by any variables, and $t$ stands for any term. (There are some minor syntactic restrictions on $x$ and $t$ in the last two logical axioms.) In other words there are actually infinitely many axioms, each one of which fits one of the formats given above.

The formal system is completed by specifying two rules of inference:

- from $\phi$ and $\phi \rightarrow \psi$, infer $\psi$
- from $\phi$, infer $(\forall x)\phi$

which are also presented schematically. A theorem of PA is any formula which is either an axiom or follows from other theorems by a rule of inference.

Peano arithmetic attains a perfect degree of formality. It would not be difficult to write a computer program which would mechanically list all theorems of the system. The question of whether some statement is or is not a theorem is completely precise and might even be characterized as a combinatorial question.

In the twentieth century mathematicians decided that set theory is the fundamental subject in terms of which all ordinary mathematics should in principle be interpreted. [Editorial comment: This may have been a mistake. Philosophically, the concept of a set was never very convincing and seemed to arise out of elementary grammatical confusions. (Halmos: “A pack of wolves, a bunch of grapes, or a flock of pigeons are all examples of sets of things.” Black: “It ought then to make sense, at least sometimes, to speak of being pursued by a set, or eating a set, or putting a set to flight.”) Moreover, proof theorists now know that all or virtually all mainstream mathematics can be formalized in essentially number-theoretic systems that are metaphysically unexceptionable. However, even if set theory does not really belong in the foundational role in which it is currently cast, it is still a beautiful and fascinating subject worthy of study in its own right.]

The formal language of set theory is even simpler than the language of Peano arithmetic. The only atomic formulas are $x \in y$ and $x = y$ (for any variables $x$ and $y$). Arbitrary formulas are built up from the atomic ones using, say, the symbols $\rightarrow$, $\neg$, and $\forall$ just as in Peano arithmetic. The rules of inference and the logical axioms are also the same as those of PA, except that now variables are the only terms. The standard non-logical axioms of set theory — the Zermelo-Fraenkel axioms including the axiom of choice (ZFC) — are not quite so neat, however. Several of them become fairly unreadable when expressed formally. We will state them informally, but it should be clear that formalizing them would be routine.
Zermelo-Fraenkel axioms

1. **Extensionality.** For all x and y, x = y if and only if they have the same elements.
2. **Pairing.** For all x and y there exists a set \{x, y\} whose elements are exactly x and y.
3. **Separation scheme.** For all x there exists a set \{u \in x : \phi(u)\} whose elements are exactly those sets in x which satisfy \phi. (One axiom for each formula \phi.)
4. **Union.** For all x there exists a set y = \bigcup_{u \in x} u, the union of all u \in x.
5. **Power set.** For all x there exists a set y = \mathcal{P}(x), the set of all subsets of x.
6. **Infinity.** There exists an infinite set.
7. **Replacement scheme.** If for every u there is at most one v such that \phi(u,v), then for every x there exists a set y whose elements are exactly those v such that \phi(u,v) for some u \in x. (One axiom for each formula \phi.)
8. **Foundation.** Every nonempty set has an \epsilon-minimal element.
9. **Choice.** Every nonempty set of nonempty sets has a choice function.

We also need an axiom about equality which states that for all x, y, and z, if x = y and x \in z then y \in z.

(Technical point: in separation and replacement the formula \phi could have free variables other than those indicated. If \phi has other free variables x_1,\ldots,x_n then the axioms should be understood as asserting that for all x_1,\ldots,x_n the stated assertion holds.)

Our goal is to prove that various statements are consistent with or independent of ZFC. The example of the parallel postulate mentioned above illustrates the basic idea: **models.** We want to show that the continuum hypothesis (CH) is consistent with ZFC by constructing a model of ZFC + CH — a structure in which both the ZFC axioms and the continuum hypothesis hold — and that it is independent of ZFC by also constructing a model of ZFC + \neg CH. This is exactly how we show that the parallel postulate and its negation are both consistent with the other Euclidean axioms. The obvious problem in the case of set theory is that it is not clear that there are any models of ZFC at all. We get around this difficulty by assuming that ZFC has models. We then use the technique of **forcing** to convert a given model of ZFC into a model of ZFC plus some other statement \phi. The result is a theorem which states “if ZFC is consistent, then so is ZFC + \phi.” We say that \phi is relatively consistent with ZFC.

It is easy to get confused about where these arguments take place. A model is a set-theoretic object, so are we reasoning in ZFC the whole time? Is it legitimate to reason about the existence of models of ZFC within ZFC? If we are working in ZFC, then aren’t we taking the consistency of ZFC as given? There are various ways of answering these concerns. We will use the following device. We define a new formal system ZFC* which is, roughly, ZFC augmented by the assumption that ZFC has a countable transitive model M. (X is transitive if for every x \in X, every element of x is also an element of X.) The bulk of our work will take place within ZFC*. Specifically, we carry out all forcing arguments in ZFC*; this is where we convert M into a new countable transitive model M[G] in which the desired statement \phi is also true. Having done this, we then step outside of ZFC* and argue that if ZFC + \phi were not consistent then ZFC* would not be consistent, and hence ZFC would not be consistent. Thus, consistency of ZFC implies consistency of ZFC + \phi. This last step requires no set theory and can be formalized in PA.

In short, a typical forcing argument is carried out in ZFC* and proves, in ZFC*, that there is a model M[G] of ZFC + \phi, for some statement \phi. Given that this result has a proof in ZFC*, we can, using only finitistic methods, draw the conclusion that if ZFC is consistent then so is ZFC + \phi. The end result is a theorem of Peano arithmetic, but the main part of the proof is a set-theoretic argument in ZFC*.

2. Well-ordered sets

This section takes place entirely within ZFC.

Definition 2.1. A well-ordered set is a totally ordered set \( W \) with the following property: for any subset \( S \subseteq W \), if there exists \( a \in W \) such that \( x < a \) for all \( x \in S \), then there exists a least such \( a \).

In other words, if \( S \) has any strict upper bounds then it has a minimal strict upper bound. Or: every subset has an immediate successor, if it has any successors. The significance of this condition is that we can carry out inductive proofs and recursive constructions along \( W \). By the well-ordering property, however far we have carried out a construction there will always be a next step.

Any nonempty well-ordered set \( W \) has a smallest element since \( \emptyset \subseteq W \) has a least upper bound. If \( W \) has more than one element, then the first element has an immediate successor, and so on. If \( W \) contains a sequence of elements \( a_1, a_2, a_3, \ldots \) where \( a_1 \) is the smallest element, \( a_2 \) is the immediate successor of \( a_1 \), \( a_3 \) is the immediate successor of \( a_2 \), etc., then either \( W = \{a_n : n \in \mathbb{N}\} \) (and \( W \) is order-isomorphic to \( \mathbb{N} \)), or else the sequence \( (a_n) \) has an immediate successor \( a_\omega \). If this does not exhaust \( W \) then \( a_\omega \) must have an immediate successor \( a_{\omega+1} \), and so on.

Theorem 2.2. Let \( W \) be a totally ordered set. The following are equivalent:

(a) \( W \) is well-ordered;
(b) there is no strictly decreasing sequence in \( W \);
(c) every nonempty subset of \( W \) has a smallest element.

Proof. (a) \( \Rightarrow \) (b). Suppose \( W \) is well-ordered and \( (a_n) \subseteq W \) is strictly decreasing, i.e., \( a_1 > a_2 > \cdots \). Define

\[ S = \{x \in W : x < a_n \text{ for all } n\}. \]

By the well-ordering property this set has an immediate successor \( a \). Since every \( a_n \) is a strict upper bound for \( S \), it follows that \( a_n \geq a \) for all \( n \), and since the \( a_n \) are decreasing we must then have \( a_n > a \) for all \( n \). But then \( a \in S \), a contradiction.

(b) \( \Rightarrow \) (c). Exercise.

(c) \( \Rightarrow \) (a). Suppose (c) holds and let \( S \subseteq W \) be a subset which has a strict upper bound. Let \( T \) be the set of all strict upper bounds,

\[ T = \{y \in W : x < y \text{ for all } x \in S\}. \]

Then (c) implies that \( T \) has a smallest element, i.e., \( S \) has an immediate successor. This shows that \( W \) is well-ordered.

Corollary 2.3. Any subset of a well-ordered set is well-ordered (with the inherited order).

Proof. Immediate from Theorem 2.2 (b), say.

The basic result on well-ordered sets is Theorem 2.7. It requires a definition and two lemmas. In the following “isomorphism” means “order-isomorphism”.

Definition 2.4. Let \( W \) be a well-ordered set. An initial segment of \( W \) is a set of the form \( x^\prec = \{y \in W : y < x\} \), for some \( x \in W \).

Lemma 2.5. No well-ordered set is isomorphic to an initial segment of itself.

Proof. Let \( W \) be a well-ordered set and let \( a \in W \). Suppose \( f : W \to a^\prec \) is an isomorphism. Then \( f(a) < a \), and inductively \( f^{n+1}(a) < f^n(a) \) for any \( n \in \mathbb{N} \) since \( f \) is an isomorphism. Thus the sequence \( a > f(a) > f^2(a) > \cdots \) is strictly decreasing, which contradicts Theorem 2.2 (b).
Lemma 2.6. Suppose $V$ and $W$ are isomorphic well-ordered sets. Then the isomorphism between them is unique.

Proof. Given two isomorphisms $f, g : V \rightarrow W$, let $h = g^{-1} \circ f : V \rightarrow V$. For any $x \in V$, the map $h$ establishes an isomorphism between $x^<$ and $h(x)^<$, so Lemma 2.5 implies that $x = h(x)$. This shows that $h$ must be the identity map, and hence $f = g$. ■

Theorem 2.7. Let $V$ and $W$ be well-ordered sets. Then either (1) $V$ is isomorphic to an initial segment of $W$; (2) $W$ is isomorphic to an initial segment of $V$; or (3) $V$ and $W$ are isomorphic.

Proof. Let $f = \{ (x, y) \in V \times W : x^< \text{ is isomorphic to } y^< \}$. By Lemma 2.5, for each $x \in V$ there is at most one such $y \in W$, and conversely; thus $f$ is a bijection between a subset of $V$ and a subset of $W$. It is easy to check that $f$ preserves order.

If $x^<$ is isomorphic to $y^<$ then for any $z_0 < x$ there exists $y_0 < y$ such that $x_0^<$ and $y_0^<$ are isomorphic. Thus, the domain of $f$ is either $V$ or an initial segment of $V$, and similarly the image of $f$ is either $W$ or an initial segment of $W$.

If either the domain of $f$ is $V$ or the range of $f$ is $W$ then we are done. So suppose both are initial segments, say $x^< \subseteq V$ and $y^< \subseteq W$. But then $f$ is an isomorphism between $x^<$ and $y^<$, which means the pair $(x, y)$ belongs to $f$, which is a contradiction. ■

Now we prove that well-orderings exist in abundance.

Definition 2.8. Let $X$ be a set all of whose elements are nonempty sets. A choice function for $X$ is a function $f$ with domain $X$ such that $f(x) \in x$ for all $x \in X$.

(Recall that the axiom of choice asserts that every set of nonempty sets has a choice function.)

Theorem 2.9. Every set can be well-ordered.

Proof. Let $X$ be a set. By the axiom of choice, let $f$ be a choice function for the set of all nonempty subsets of $X$. Call a subset $A \subseteq X$ a Zermelo set if there is a well-ordering on $A$ which has the property that every $x \in A$ satisfies $x = f(X - x^<)$. (For instance, $\emptyset$, $\{ f(X) \}$, and $\{ f(X), f(X - \{ f(X) \}) \}$ are all Zermelo sets.)

We first claim that if $A$ and $B$ are isomorphic Zermelo sets, then $A = B$ and the isomorphism is the identity map. To see this let $g : A \rightarrow B$ be an isomorphism, assume $g$ is not the identity map, and let $x$ be the smallest element of $A$ such that $x \neq g(x)$. Then $x^< = g(x)^<$, so

$$x = f(X - x^<) = f(X - g(x)^<) = g(x)$$

(using the fact that $A$ and $B$ are both Zermelo). This is a contradiction, so we conclude that $A = B$ and the isomorphism is the identity map.

Since any initial segment of a Zermelo set is itself a Zermelo set, it now follows from Theorem 2.7 that if $A$ and $B$ are any Zermelo sets, then either $A$ is an initial segment of $B$, $B$ is an initial segment of $A$, or $A = B$.

We now claim that the union $Z$ of all Zermelo sets is itself a Zermelo set. Indeed, if $x$ is an element of any Zermelo set $A$, then by the previous paragraph the initial segment $x^<$ is the same in any Zermelo set that contains $x$. Thus

$$\{ y \in Z : y < x \} = \{ y \in A : y < x \}.$$

So the fact that $x = f(X - x^<)$ in $A$ implies the same in $Z$, and hence $Z$ is Zermelo.

Finally, $Z$ must equal $X$. Otherwise the set $X - Z$ would be nonempty, and the set $Z \cup \{ f(X - Z) \}$ would be a Zermelo set not contained in $Z$, a contradiction. We conclude that $X$ is well-ordered. ■
Exercises

(a) Prove Theorem 2.2 \( \Rightarrow \) (c).
(b) Let \( W_1 \subseteq W_2 \subseteq \cdots \) be a nested sequence of well-ordered sets. Assume that for all \( n \) the order on \( W_n \) agrees with the order it inherits from \( W_{n+1} \). Thus, we obtain a total order on \( W = \bigcup_{n}^\infty W_n \). Is it necessarily a well-ordering?
(c) Work in ZF (all the axioms of ZFC except the axiom of choice). Assuming that every set can be well-ordered, prove the axiom of choice.

3. Ordinals and cardinals

This section takes place entirely within ZFC.

Ordinals are a certain kind of canonical well-ordered set. Informally, every well-ordered set \( W \) can be converted into an ordinal in the following way. If \( W \) is nonempty then it has a first element; replace it with \( \emptyset \). If \( W \) has a second element, replace it with \( \{\emptyset\} \). If \( W \) has a third element, replace it with \( \{\emptyset, \{\emptyset\}\} \).

In general, having replaced every element which precedes \( x \in W \), replace \( x \) with \( \{y \in W : y < x\} \). This makes sense both at successor points and at limit points, so we can continue until \( W \) is exhausted. We now formalize this assertion.

Definition 3.1. A set \( X \) is transitive if for any \( x \in X \), every element of \( x \) is also an element of \( X \). (Equivalently: \( x \in X \) implies \( x \subseteq X \).) An ordinal is a transitive set which is well-ordered by \( \in \). We order the ordinals by letting \( \alpha < \beta \) if \( \alpha \in \beta \).

Proposition 3.2. Every well-ordered set is order-isomorphic to an ordinal. If \( \alpha \) and \( \beta \) are ordinals then exactly one of \( \alpha < \beta \), \( \alpha = \beta \), \( \alpha > \beta \) is true.

Proof. Exercise.

Every ordinal is the set of all smaller ordinals. Thus, the first few ordinals are

\[ \emptyset, \ \{\emptyset\}, \ \{\emptyset, \{\emptyset\}\}, \ \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}, \ldots. \]

We set-theoretically encode the natural numbers as finite ordinals by letting \( 0 = \emptyset \), \( 1 = \{\emptyset\} \), etc., in general letting \( n + 1 = \{0, \ldots, n\} \). The first infinite ordinal is

\[ \omega = \mathbb{N} = \{0, 1, 2, \ldots\} \]

and its immediate successor is \( \omega + 1 = \omega \cup \{\omega\} \). (In general the successor of \( \alpha \) is \( \alpha \cup \{\alpha\} \).) The first uncountable ordinal is denoted \( \omega_1 \).

We are working in ZFC, and we now state a “theorem scheme” addressing induction and recursion on the ordinals. For any formulas \( \phi \) and \( \psi \) in the language of set theory, the following is a theorem of ZFC.

Theorem 3.3.

(a) Suppose that for any ordinal \( \alpha \)

\[ (\forall \beta < \alpha) \phi(\beta) \rightarrow \phi(\alpha). \]

Then \( \phi(\alpha) \) holds for all ordinals \( \alpha \).
(b) Let \( a \) be a set. Suppose that for any nonzero ordinal \( \alpha \) and any set \( x \) there is a unique set \( y \) such that \( \psi(\alpha, x, y) \) is true. Then for any ordinal \( \alpha \) there is a unique set \( a_\alpha \) such that (1) \( a_0 = a \) and (2) for all \( \alpha > 0 \), \( a_\alpha \) satisfies \( \psi(\alpha, \bigcup_{\beta < \alpha} a_\beta, a_\alpha) \).
Proof. (a) Suppose \( \phi(\alpha) \) fails for some \( \alpha \). Let \( S = \{ \beta < \alpha : \phi(\beta) \) is false\}. Then \( S \) has a least element \( \beta \), and \( \phi(\gamma) \) holds for all \( \gamma < \beta \) but \( \phi(\beta) \) is false, contradicting the hypothesis. So \( \phi(\alpha) \) must be true for all \( \alpha \).

(b) Uniqueness of the sequence follows from part (a) (induction on \( \alpha \)). For existence, let \( \phi(\alpha, a, x) \) be the formula “\( \alpha \) is an ordinal and \( x \) is a sequence of sets \( (a_\beta)_{\beta < \alpha} \) such that \( a_0 = a \) and \( \psi(\beta, \bigcup_{\gamma < \beta} a_\gamma, a_\beta) \) holds for all \( \beta < \alpha \).” Then apply part (a) to the formula \( (\exists x)\phi(\alpha, a, x) \).

For instance, the power set axiom states that every set has a power set, and by the extensionality axiom power sets are unique. Taking \( \psi(\alpha, x, y) \) to be “if \( \alpha \) is a successor then \( y = \mathcal{P}(x) \), and if \( \alpha \) is a limit then \( y = x^\alpha \)” and letting \( a = \emptyset \) yields the cumulative hierarchy \( (V_\alpha) \) where \( V_0 = \emptyset \), \( V_{\alpha+1} = \mathcal{P}(V_\alpha) \) for all \( \alpha \), and \( V_\alpha = \bigcup_{\beta < \alpha} V_\beta \) when \( \alpha \) is a limit ordinal. The rank of a set \( x \) is the smallest value of \( \alpha \) such that \( x \in V_\alpha \).

(Exercise: every set belongs to some \( V_\alpha \).)

**Definition 3.4.** A cardinal is an ordinal that cannot be put in bijection with any smaller ordinal.

Thus every finite ordinal (i.e., \( 0, 1, 2, \ldots \)) is a cardinal. Also \( \omega \) is a cardinal, but \( \omega + 1 \) is not. Indeed, the next cardinal after \( \omega \) is \( \omega_1 \). We also write \( \aleph_0 = \omega \), \( \aleph_1 = \omega_1 \), and in general \( \aleph_\alpha = \text{the } \alpha \text{th infinite cardinal} \).

**Proposition 3.5.** Every set can be put in bijection with a unique cardinal.

**Proof.** Exercise.

**Definition 3.6.** For any set \( X \), \( \text{card}(X) \) is the unique cardinal in bijection with \( X \). If \( \lambda \) and \( \kappa \) are cardinals then we define

(a) \( \lambda + \kappa = \text{card}(\lambda \bigcup \kappa) \) (the cardinality of their disjoint union),
(b) \( \lambda \cdot \kappa = \text{card}(\lambda \times \kappa) \) (the cardinality of their cartesian product), and
(c) \( \lambda^\kappa = \text{card}(\{ \text{all functions from } \kappa \text{ into } \lambda \}) \).

To see the reasonableness of the last definition, observe that if \( m \) and \( n \) are natural numbers then the number of functions from an \( n \)-element set into an \( m \)-element set is \( m^n \). (Each element of the domain has \( m \) possible target values.)

We collect some elementary properties of cardinal arithmetic, with proofs left to the reader.

**Proposition 3.7.** Let \( \lambda, \kappa, \text{ and } \theta \) be cardinals. Then

(a) \( \lambda + \kappa = \kappa + \lambda \);
(b) \( \lambda + (\kappa + \theta) = (\lambda + \kappa) + \theta \);
(c) \( \lambda \cdot \kappa = \kappa \cdot \lambda \);
(d) \( \lambda \cdot (\kappa \cdot \theta) = (\lambda \cdot \kappa) \cdot \theta \);
(e) \( \lambda \cdot (\kappa + \theta) = \lambda \cdot \kappa + \lambda \cdot \theta \);
(f) \( \lambda^{\kappa + \theta} = \lambda^\kappa \cdot \lambda^\theta \);
(g) \( (\lambda + \kappa)^\theta = \lambda^\theta \cdot \kappa^\theta \).

Observe that every subset of a set \( X \) determines a function from \( X \) into \( 2 = \{ 0, 1 \} \), namely its characteristic function; and conversely, every function from \( X \) into \( 2 \) is the characteristic function of some subset of \( X \).

Thus

\[ 2^\text{card}(X) = \text{card}(\{ \text{functions from card}(X) \text{ into } 2 \}) \]
\[ = \text{card}(\{ \text{functions from } X \text{ into } 2 \}) \]
\[ = \text{card}(\mathcal{P}(X)). \]

The two basic results on cardinal arithmetic are the following.

**Theorem 3.8.** Let \( \kappa \) be a cardinal. Then \( \kappa < 2^\kappa \).
Proof. By the comment preceding the theorem, we must show that for any set $X$ there is an injective map from $X$ into $\mathcal{P}(X)$, but no bijection between $X$ and $\mathcal{P}(X)$. The first task is easy: take $x \in X$ to $\{x\} \in \mathcal{P}(X)$. Now suppose $f : X \to \mathcal{P}(X)$ is any map. Let $A = \{x \in X : x \notin f(x)\}$. Then for any $x \in X$ we have $x \in f(x)$ if and only if $x \notin A$, so $f(x)$ cannot equal $A$ for any $x \in X$. Thus, there is no map from $X$ onto $\mathcal{P}(X)$.

**Theorem 3.9.** Let $\kappa$ be an infinite cardinal. Then $\kappa = \kappa^2$.

*Proof.* Observe that $\kappa^2 = \kappa \cdot \kappa$. We prove the theorem by induction. We already know that $\aleph_0 = \aleph_0^2$. Now let $\alpha$ be a nonzero ordinal and assume that $\aleph_\beta = \aleph_\beta^2$ for all $\beta < \alpha$. It is easy to see that $\aleph_\alpha \leq \aleph_\alpha^2$. For the reverse inequality, define

$$W = \{ \langle x, y \rangle \in \aleph_\alpha^2 : y \leq x \};$$

with the lexicographic order (that is, $\langle x_1, y_1 \rangle < \langle x_2, y_2 \rangle$ if either $x_1 < x_2$ or $x_1 = x_2$ and $y_1 < y_2$) this is a well-ordered set. Any initial segment of $W$ is isomorphic to a subset of $\gamma^\omega$ for some ordinal $\gamma < \aleph_\alpha$, and hence by hypothesis has cardinality strictly less than $\aleph_\alpha$. Thus, the ordinal that is isomorphic to $W$ (Proposition 3.2) is contained in $\aleph_\alpha$, and hence $\text{card}(W) \leq \aleph_\alpha$. It easily follows that $\aleph_\alpha^2 \leq \aleph_\alpha$.

**Corollary 3.10.** For any infinite cardinals $\lambda$ and $\kappa$, we have $\lambda \cdot \kappa = \lambda + \kappa = \max(\lambda, \kappa)$.

*Proof.* Without loss of generality suppose $\lambda \geq \kappa$. Then $\lambda \leq \lambda + \kappa \leq 2\lambda \leq \lambda \cdot \kappa \leq \lambda^2 = \lambda$.

**Corollary 3.11.** For any infinite cardinal $\lambda$, we have $2^\lambda = \lambda^\lambda = (2^\lambda)^\lambda$.

*Proof.* We have $2^\lambda \leq \lambda^\lambda \leq (2^\lambda)^\lambda = 2^{\lambda^\lambda} \leq 2^\lambda$.

Since $\text{card}(\mathbb{R}) = \text{card}(\mathcal{P}(\mathbb{N})) = 2^{\aleph_0}$, Theorem 3.8 implies that $2^{\aleph_0} \geq \aleph_1$. The **continuum hypothesis (CH)** is the assertion that $2^{\aleph_0} = \aleph_1$. We will see that CH cannot be decided in ZFC.

**Exercises**

(a) Prove Proposition 3.2.
(b) Let $\alpha$ be an ordinal. Prove that the successor ordinal is $\alpha \cup \{\alpha\}$.
(c) Prove that every set belongs to some $V_\alpha$.
(d) Prove Proposition 3.5.
(e) Use cardinal arithmetic to prove that the cardinality of the set of all countable subsets of $\mathbb{R}$ equals the cardinality of $\mathbb{R}$.

**4. Relativization, reflection, and collapse**

This section takes place entirely within ZFC.

We would like to have sets that can play the role of “miniature universes”. In principle any set $M$ can be thought of this way, but the better closure properties $M$ has the more realistically it will mimic the real universe of sets. Ideally we would like all the axioms of ZFC to be “true in $M$”. What this means is explained in the following definition.

**Definition 4.1.** Let $M$ be a set and let $\phi$ be a formula in the language of set theory. The **relativization of $\phi$ to $M$**, denoted $\phi^M$, is the formula obtained from $\phi$ by replacing every quantifier with its restriction to $M$. That is, replace every $(\forall x)$ with $(\forall x \in M)$ and replace every $(\exists x)$ with $(\exists x \in M)$. If a set $S$ is defined by proving

$$\exists x \phi(x)$$

where $\phi$ has only one free (unquantified) variable $x$, and letting $S$ be the unique $x$ satisfying $\phi(x)$, then we can define the relativization of $S$ to $M$ by proving

$$\exists x \in M \phi^M(x)$$
and letting $S^M$ be the unique $x \in M$ satisfying $\phi^M(x)$. If there are no free variables in $\phi$ (it is a sentence), then we say that $\phi$ is true in $M$ or that $M$ satisfies $\phi$, written $M \models \phi$, if $\phi^M$ is true. More generally, if the free variables of $\phi$ are among $x_1, \ldots, x_n$ and $u_1, \ldots, u_n \in M$ then we say that $\phi(u_1, \ldots, u_n)$ is true in $M$ and write $M \models \phi(u_1, \ldots, u_n)$ if $\phi^M(u_1, \ldots, u_n)$ is true.

Note that the definition of $S^M$ is ambiguous, since the set $S$ might be definable using another formula $\psi$ whose relativization to $M$ is not equivalent to $\phi^M$. Also note that in general $S^M$ need not exist. But both of these problems effectively disappear if all the axioms of ZFC are true in $M$, since then (1) two formulas that are provably equivalent outside $M$ are also provably equivalent inside $M$, and (2) if we can prove the existence of $S$ outside $M$ then we can prove the existence of $S^M$ inside $M$.

Next we take up the problem of finding sets $M$ in which various formulas $\phi$ are true. We do this by the reflection principle (Theorem 4.3).

For any finite list of formulas $\phi_1, \ldots, \phi_n$ whose free variables are among $x, x_1, \ldots, x_k$, the following is provable in ZFC.

**Lemma 4.2.** Let $M_0$ be a countable set. Then there is a countable set $M$ which contains $M_0$, such that for every $u_1, \ldots, u_k \in M$ we have

$$(\exists x)\phi_1(x, u_1, \ldots, u_k) \quad \text{implies} \quad (\exists x \in M)\phi_1(x, u_1, \ldots, u_k).$$

$$
\vdots
$$

$$(\exists x)\phi_n(x, u_1, \ldots, u_k) \quad \text{implies} \quad (\exists x \in M)\phi_n(x, u_1, \ldots, u_k).$$

**Proof.** The set of $k$-tuples $\langle u_1, \ldots, u_k \rangle \in M_0^k$ is countable. Construct a set $M_1$ by adding to $M_0$, for each $i$ and each such $k$-tuple, a value of $x$ such that $\phi_i(x, u_1, \ldots, u_k)$, if any such value exists. Then $M_1$ is also countable, and hence so is the set of $k$-tuples in $M_1$. Construct a set $M_2$ by adding to $M_1$, for each $i$ and each such $k$-tuple, a value of $x$ such that $\phi_i(x, u_1, \ldots, u_k)$, if any such value exists. Continue recursively and let $M = \bigcup_0^\infty M_j$. Then $M$ is a countable union of countable sets and hence is countable. Now suppose that for some $u_1, \ldots, u_k \in M$ there exists $x$ such that $\phi_i(x, u_1, \ldots, u_k)$. Then $u_1, \ldots, u_k$ lie in $M_j$ for some $j$, and by the construction of $M_{j+1}$ there exists $x \in M_{j+1}$ satisfying $\phi_i(x, u_1, \ldots, u_k)$. So there exists such an $x$ in $M$.

For any finite list of sentences $\phi_1, \ldots, \phi_n$ which are provable in ZFC, the following is a theorem of ZFC.

**Theorem 4.3.** Let $M_0$ be a countable set. Then there is a countable set $M$ which contains $M_0$, such that $M \models \phi_1 \land \cdots \land \phi_n$.

**Proof.** Let $\psi_1, \ldots, \psi_m$ be a list of formulas that contains the sentences $\phi_1, \ldots, \phi_n$ and is subformula closed, meaning that if $\neg \phi$ is in the list, so is $\phi$; if $\phi \land \psi$ is in the list, so are $\phi$ and $\psi$; if $(\forall x)\phi$ is in the list, so is $\phi$, etc. We can no longer assume the $\psi_i$ are sentences. We will find $M$ such that that for each $\psi_i$ in the list with free variables $x_1, \ldots, x_k$, we have

$$\psi_i(u_1, \ldots, u_k) \leftrightarrow \psi_i^M(u_1, \ldots, u_k) \quad (\ast)$$

for any $u_1, \ldots, u_k \in M$. If $\psi_i$ has no free variables, this means $\psi_i \leftrightarrow \psi_i^M$, so the truth of $\phi_1, \ldots, \phi_n$ implies the truth of $\phi_1^M, \ldots, \phi_n^M$.

Apply Lemma 4.2 to $\psi_1, \ldots, \psi_m$ to obtain the desired set $M$. We prove $(\ast)$ by induction on the complexity of the formulas $\psi_i$. If $\psi_i$ is atomic then $(\ast)$ is trivial. If $(\ast)$ holds for $\phi$ and $\psi$ then it trivially holds for $\neg \phi$, $\phi \land \psi$, and $\phi \lor \psi$. Finally, the content of Lemma 4.2 is that if $(\ast)$ holds for $\phi$ then it holds for $(\exists x)\phi$. This completes the proof. (We need not consider universal quantification separately, since $(\forall x)\phi$ is logically equivalent to $\neg (\exists x)\neg \phi$)
In particular, if \( \phi_1, \ldots, \phi_n \) are among the axioms of ZFC then we can prove, in ZFC, the existence of a countable set \( M \) in which \( \phi_1, \ldots, \phi_n \) are true. We say that there is a model of any finite fragment of ZFC. This result is best possible since, assuming ZFC is consistent, we cannot prove in ZFC that ZFC has a model — this is a consequence of Gödel’s second incompleteness theorem. But merely having a model of any finite fragment is a very strong result, since any theorem of ZFC is proven using only finitely many axioms. Hence any theorem of ZFC, or any finitely many theorems of ZFC, are provably true in some countable set \( M \).

It is convenient to work with models that are transitive (see Definition 3.1), and this can always be arranged provided \( M \) is extensional, meaning that for any distinct \( x, y \in M \) there exists \( u \in M \) either in \( x \) but not \( y \) or in \( y \) but not \( x \). (Equivalently: the axiom of extensionality is true when relativized to \( M \).) The technique that achieves transitivity is called Mostowski collapse. This is essentially a generalization of the fact that every well-ordered set is order-isomorphic to an ordinal (Proposition 3.2).

**Theorem 4.4.** Let \( M \) be an extensional set. Then there is a transitive set \( N \) and a bijection \( f : M \to N \) such that \( x \in y \) in \( M \) if and only if \( f(x) \in f(y) \) in \( N \).

**Proof.** Say that a set \( M_0 \subseteq M \) is Mostowski if it is downward closed (i.e., if \( x \in M_0 \) then any \( u \in M \) that is in \( x \) is in \( M_0 \)) and there is a transitive set \( N_0 \) and a bijection \( f_0 : M_0 \to N_0 \) such that \( x \in y \) in \( M_0 \) if and only if \( f_0(x) \in f_0(y) \) in \( N_0 \).

Exercise: if \( M_0 \) is Mostowski then the \( N_0 \) and \( f_0 \) which verify this fact are unique. The intersection of any two Mostowski sets is Mostowski, and the corresponding bijections with transitive sets agree on the intersection. Any union of Mostowski sets is Mostowski.

Let \( M' \) be the union of all Mostowski sets. It follows from the preceding paragraph that \( M' \) is Mostowski. Let \( f : M' \to N \) be the bijection that verifies this and suppose \( M' \neq M \). By the axiom of foundation there is an \( \epsilon \)-minimal element \( x \) of \( M - M' \). Let \( y = \{ f(u) : u \in x \cap M \} \). It is then straightforward to verify that \( M' \cup \{ x \} \) is Mostowski via a bijection with \( N \cup \{ y \} \), contradicting maximality of \( M' \). Thus \( M' = M \), which verifies the theorem.

The fact that \( M \) and \( N \) are isomorphic in the sense of the theorem means that \( \phi^M \) will be true if and only if \( \phi^N \) is true, for any sentence \( \phi \). Thus, combining the reflection principle with Mostowski collapse yields the next corollary. For any finite list of sentences \( \phi_1, \ldots, \phi_n \) which are provable in ZFC, the following is provable in ZFC.

**Corollary 4.5.** There is a countable transitive set \( M \) such that \( M \models \phi_1 \land \cdots \land \phi_n \).

**Exercises**

(a) In the proof of Theorem 4.3, make explicit the argument that if \((*)\) holds for \( \phi \) then it holds for \((\exists x)\phi\).

(b) In the proof of Theorem 4.4, prove that if \( M_0 \) is Mostowski then the \( N_0 \) and \( f_0 \) which verify this fact are unique. (Hint: use the axiom of foundation.) Prove that the intersection of any two Mostowski sets is Mostowski, and the corresponding bijections with transitive sets agree on the intersection. Use this to show that any union of Mostowski sets is Mostowski.

5. Finitistic consistency proofs

This section is finitistically valid. All results could be formalized in PA.

All forcing arguments will take place in the formal system ZFC*, which we define now.

**Definition 5.1.** The language of ZFC* is the language of ZFC together with one constant symbol \( M \). The atomic formulas of ZFC* are all formulas of the form \( x \in y \) or \( x = y \), where \( x \) and \( y \) can be replaced by any variables, plus all such formulas in which either or both variables are replaced by \( M \). The formulas of ZFC* are built up from the atomic formulas in the usual way. The axioms of ZFC* come in four categories:
(a) every axiom of ZFC is also an axiom of ZFC*;
(b) \((\forall x)\phi(x) \rightarrow \phi(M)\) is an axiom of ZFC* for every formula \(\phi\) and any variable in place of \(x\);
(c) the statement “\(M\) is countable and transitive” is an axiom of ZFC*;
(d) the relativization of any axiom of ZFC to \(M\) is an axiom of ZFC*.

In effect, ZFC* is ZFC augmented by the fact that there is a countable transitive set \(M\) which models ZFC. However, the way this fact is formalized is slightly subtle. Working in ZFC*, we have a countable transitive set \(M\), and for any axiom \(\phi\) of ZFC we know that \(\phi\) is true in \(M\). But (assuming ZFC* is consistent) we cannot prove in ZFC* a single statement to the effect that all axioms of ZFC are true in \(M\). This is good because if we could do this, then in ZFC* we could prove the consistency of ZFC, and Gödel's second incompleteness theorem would then prevent us from being able to prove the following result.

**Lemma 5.2.** If ZFC is consistent, so is ZFC*.

*Proof.* Suppose ZFC* is inconsistent. Then there is a proof of \(\phi \land \neg \phi\) for some formula \(\phi\). This proof involves only finitely many axioms of type (d) in Definition 5.1, say \(\phi_M^1, \ldots, \phi_M^n\) where \(\phi_1, \ldots, \phi_n\) are axioms of ZFC.

By Corollary 4.5, we can prove in ZFC that there is a countable transitive set \(M\) such that \(\phi_M^1, \ldots, \phi_M^n\) are true. Having done this, we can then copy in ZFC the original proof of \(\phi \land \neg \phi\) in ZFC*, everywhere replacing \(M\) with \(M\). The result is a proof in ZFC of a contradiction. Thus, we have shown that any inconsistency in ZFC* could be mechanically converted into an inconsistency in ZFC.

In a typical forcing argument, we will work in ZFC* and enlarge the set \(M\) to another countable transitive set \(M[G]\), in such a way that we ensure that some special formula \(\phi\) (e.g., the continuum hypothesis) is true in \(M[G]\). For any axiom \(\psi\) of ZFC, we will also be able to show that \(\psi\) is true in \(M[G]\). (But again, we cannot prove a single statement to the effect that all axioms of ZFC are true in \(M[G]\).) This gives us the hypothesis of the following theorem.

**Theorem 5.3.** Let \(\phi\) be a formula in the language of ZFC. Suppose that in ZFC* we can define a countable transitive set \(N\) such that (1) in ZFC* we can prove \(\phi^N\) and (2) for any axiom \(\psi\) of ZFC, in ZFC* we can prove \(\psi^N\). Then if ZFC is consistent, so is ZFC + \(\phi\).

*Proof.* Suppose ZFC + \(\phi\) is not consistent. Then there is a proof in ZFC + \(\phi\) of some contradiction. Since in ZFC* we can prove the relativization of \(\phi\) to \(N\) as well as the relativization of any axiom of ZFC to \(N\), we can relativize the entire proof of the contradiction to \(N\) and this becomes a valid proof in ZFC* of a contradiction. So ZFC* is not consistent. By the lemma, it then follows that ZFC is not consistent. Thus, we have shown that any inconsistency in ZFC + \(\phi\) could be mechanically converted into an inconsistency in ZFC.

---

**6. Generic extensions**

*From this point on, except in applications sections we work in ZFC*. We have a countable transitive set \(M\) in which the axioms of ZFC are true. We would like to enlarge it by adding in a structure that makes some desired additional assertion true. For example, we may want to add a bijection between \(\mathcal{P}(\mathbb{N})\) and \(\aleph_1\) in order to make the continuum hypothesis true, or a set of \(\aleph_\alpha\) real numbers for some \(\alpha > 1\) to make the continuum hypothesis false. In order for this procedure to work it will be important that the structure being added has no “special properties” relative to the model \(M\) — it is **generic**. We ensure this by defining, in \(M\), a partially ordered set of all possible *partial constructions* of the desired structure. As we move down this partially ordered set we specify the desired structure more precisely. We can then identify a “generic” path down the poset which describes a “generic” structure of the desired type.

**Definition 6.1.** A **notion of forcing** is a preordered set \(P \in M\) (i.e., \(P\) is equipped with a relation \(\leq\) which is reflexive and transitive) with greatest element \(1_P\).
(a) If \( p,q \in P \) and \( p \leq q \) then \( p \) is an extension of \( q \). Two elements are compatible if they have a common extension.

(b) A subset \( D \) of \( P \) is dense if every \( p \in P \) has an extension in \( D \). It is dense below \( p \) if every \( q \leq p \) has an extension in \( D \).

(c) A filter of \( P \) is a subset \( G \) which is upwards closed (if \( p \in G \) and \( p \leq q \) then \( q \in G \)) and directed downwards (every pair of elements of \( G \) have a common extension in \( G \)). It is generic if \( G \cap D \neq \emptyset \) for every dense subset \( D \in M \).

Note that in the definition of generic we do not require \( G \) to meet every dense subset, only those that appear in \( M \). Indeed, suppose \( P \) satisfies the mild condition that every element of \( P \) lies above a pair of incompatible elements; then the complement of any filter is dense (exercise), so no filter meets all dense subsets. In fact, this shows that under this condition on \( P \), no generic filter can lie in \( M \) (since if it did its complement would also lie in \( M \) and this would prevent it from being generic). However, generic filters do always exist.

Lemma 6.2. Let \( P \) be a notion of forcing and let \( p_0 \in P \). Then there is a generic filter of \( P \) that contains \( p_0 \).

Proof. Since \( M \) is countable, we can enumerate all dense subsets \( D \subseteq P \) which lie in \( M \). Let \( (D_n) \) be such an enumeration. Recursively define a sequence \( (p_n) \) by choosing \( p_{n+1} \leq p_n \) in \( D_n \); we can always find such an element \( p_{n+1} \) by density of \( D_n \). Finally, let

\[
G = \{ p \in P : p_n \leq p \text{ for some } n \}.
\]

It is immediate that \( G \) is upwards closed and that it meets every dense subset in \( M \). To see that it is directed downward, let \( p,q \in G \). Then \( p_m \leq p \) and \( p_n \leq q \) for some \( m,n \). Then whichever of \( p_m \) and \( p_n \) is smaller is a common extension of \( p \) and \( q \) in \( G \). Thus \( G \) is a generic filter.

For the remainder of this section, fix a notion of forcing \( P \) and a generic filter \( G \). Our next goal is to define the set \( M[G] \). This is supposed to be the smallest transitive model of ZFC which is larger than \( M \) and contains the generic filter \( G \). We construct \( M[G] \) by first specifying names of all of its elements. These names actually lie in \( M \), but we need to use \( G \) to determine the sets that the names identify.

Definition 6.3. \( P \)-names are defined recursively by rank. Let \( \mathcal{P}_0 = \{ \emptyset \} \), and for any ordinal \( \alpha > 0 \) in \( M \) let \( \mathcal{P}_\alpha \) consist of all \( \tau \in M \) such that \( \tau \) is a set of ordered pairs of the form \( \langle \sigma,p \rangle \) with \( p \in P \) and \( \sigma \in \mathcal{P}_\beta \) for some \( \beta < \alpha \). A \( P \)-name is any element of any \( \mathcal{P}_\alpha \), and the name rank of a \( P \)-name \( \tau \) is the least \( \alpha \) such that \( \tau \in \mathcal{P}_\alpha \). The domain of a \( P \)-name \( \tau \), \( \text{dom}(\tau) \), is the set of \( \sigma \) such that \( \langle \sigma,p \rangle \in \tau \) for some \( p \in P \).

Note that since \( P \in M \) and \( M \) satisfies the axioms of ZFC, the preceding definition makes sense in \( M \), i.e., for each \( \alpha \) we have \( \mathcal{P}_\alpha \subseteq M \). (Use Theorem 3.3 (b).)

Definition 6.4. The value of a \( P \)-name \( \tau \) is defined recursively on name rank by

\[
\text{val}_G(\tau) = \{ \text{val}_G(\sigma) : \langle \sigma,p \rangle \in \tau \text{ for some } p \in G \}
\]

and \( M[G] \) is the set of values of all \( P \)-names.

When there is only one generic filter in play, we will usually write \( \text{val}(\tau) \) instead of \( \text{val}_G(\tau) \).

Definition 6.5. The \( P \)-name \( \dot{x} \) is defined recursively on rank for all \( x \in M \) by

\[
\dot{x} = \{ \langle \dot{u},1_p \rangle : u \in x \}.
\]

The \( P \)-name \( \Gamma \) is defined by

\[
\Gamma = \{ \langle \dot{p},p \rangle : p \in P \}.
\]

Proposition 6.6. \( M \subseteq M[G] \) and \( G \in M[G] \). \( M[G] \) is countable and transitive.
Proof. The first statement holds because \( \text{val}(\bar{x}) = x \) for all \( x \in M \) and \( \text{val}(\Gamma) = G \) (exercise). \( M[G] \) is countable because the set of \( P \)-names is a subset of \( M \) and hence is countable. \( M[G] \) is transitive because the value of any \( P \)-name (a typical element of \( M[G] \)) is by definition a set of values of \( P \)-names (which are themselves elements of \( M[G] \)).

We want to check that the axioms of ZFC are true in \( M[G] \). Some of them are easy, and do not even use the fact that \( G \) is generic:

**Proposition 6.7.** The axioms of extensionality, pairing, infinity, and foundation are true in \( M[G] \).

**Proof.** Extensionality follows from the fact that \( M[G] \) is transitive. Pairing holds because if \( \sigma \) and \( \tau \) are any two \( P \)-names then \( \{\langle \sigma, 1_P \rangle, \langle \tau, 1_P \rangle\} \) is a \( P \)-name whose value is \( \{\text{val}(\sigma), \text{val}(\tau)\} \). Infinity follows from the fact that \( M \subseteq M[G] \). Foundation is trivial (it is true in any set).

**Exercises**

(a) Let \( G \) be a generic filter, let \( p \in G \), and suppose \( D \in M \) is dense below \( p \). Show that \( G \cap D \neq \emptyset \).

(b) Let \( P \) be a notion of forcing in which every element lies above a pair of incompatible elements. Prove that the complement of any filter is dense.

(c) Show that \( \text{val}(\bar{x}) = x \) for all \( x \in M \) and \( \text{val}(\Gamma) = G \).

(d) Prove that every ordinal in \( M[G] \) is in \( M \).

7. The fundamental theorem of forcing

Throughout this section, fix a notion of forcing \( P \).

What makes the \( M[G] \) construction a workable technique for proving independence results is our ability to control properties of \( M[G] \), for any generic filter \( G \), using \( P \). The key concept is the following. (This is a definition scheme, depending on a formula \( \phi \) with free variables among \( x_1, \ldots, x_n \).)

**Definition 7.1.** Let \( \tau_1, \ldots, \tau_n \) be \( P \)-names and let \( p \in P \). Then \( p \) forces \( \phi(\tau_1, \ldots, \tau_n) \) if

\[
M[G] \models \phi(\text{val}_G(\tau_1), \ldots, \text{val}_G(\tau_n))
\]

for all generic filters \( G \) that contain \( p \). We write \( p \models \phi(\tau_1, \ldots, \tau_n) \).

Observe that if \( p \models \phi(\tau_1, \ldots, \tau_n) \) and \( q \leq p \) then \( q \models \phi(\tau_1, \ldots, \tau_n) \), because any generic filter that contains \( q \) also contains \( p \).

We now state the fundamental theorem of forcing. It essentially says that (a) anything that is true in \( M[G] \) is forced by some \( p \in G \) and (b) the forcing relation can be determined within \( M \). For each formula \( \phi \) with free variables among \( x_1, \ldots, x_n \) there is a formula \( \psi \) such that the following is provable in ZFC*.

**Theorem 7.2.** Let \( P \) be a notion of forcing.

(a) Let \( \tau_1, \ldots, \tau_n \) be \( P \)-names. For any generic filter \( G \), if \( M[G] \models \phi(\text{val}_G(\tau_1), \ldots, \text{val}_G(\tau_n)) \) then some \( p \in G \) forces \( \phi(\tau_1, \ldots, \tau_n) \).

(b) Let \( p, \tau_1, \ldots, \tau_n \in M \). Then \( M \models \psi(p, \tau_1, \ldots, \tau_n) \) if and only if \( \tau_1, \ldots, \tau_n \) are \( P \)-names, \( p \in P \), and \( p \models \phi(\tau_1, \ldots, \tau_n) \).

**Proof.** We will simultaneously prove (a) and (b) in the case that \( \phi = x_1 \subseteq x_2 \). For part (b), let \( \mathcal{F}_\alpha \) be the set of all triples \( \langle p, \tau_1, \tau_2 \rangle \) such that \( \tau_1 \) and \( \tau_2 \) are \( P \)-names of name rank at most \( \alpha \) and \( p \in P \) forces \( \tau_1 \subseteq \tau_2 \). It will follow from (ii) below that \( \mathcal{F}_\alpha \) can be constructed in \( M \) from \( \bigcup_{\beta < \alpha} \mathcal{F}_\beta \). This implies that the sequence \( (\mathcal{F}_\alpha) \) is definable in \( M \) (cf. Theorem 3.3 (b)), and \( \psi \) can then be taken to be a formalization of the assertion “\( \langle p, \tau_1, \tau_2 \rangle \in \mathcal{F}_\alpha \) for some ordinal \( \alpha \)”.

13
The proof goes by induction on the name ranks of \( \tau_1 \) and \( \tau_2 \). Assume that for all \( P \)-names \( \tau_1 \) and \( \tau_2 \) of name rank less than \( \alpha \) we know

(i) for any generic filter \( G \), if \( \text{val}_G(\tau_1) \subseteq \text{val}_G(\tau_2) \) then some \( p \in G \) forces \( \tau_1 \sqsubseteq \tau_2 \);

(ii) \( p \in P \) forces \( \tau_1 \sqsubseteq \tau_2 \) if and only if

\[
(\dagger) \text{ for every } (\pi_1, s_1) \in \tau_1, \text{ every element of } P \text{ that is less than both } p \text{ and } s_1 \text{ lies above some } q \in P \text{ such that } q \leq s_2 \text{ and } q \text{ forces } \pi_1 = \pi_2, \text{ for some } (\pi_2, s_2) \in \tau_2.
\]

We will verify that these also hold when one or both of \( \tau_1 \) and \( \tau_2 \) are \( P \)-names of name rank \( \alpha \). The truth of the theorem in the case that \( \phi \) is \( x_1 \subseteq x_2 \) will then follow by induction on \( \alpha \).

First let \( \tau_1 \) and \( \tau_2 \) be \( P \)-names of name rank less than or equal to \( \alpha \), let \( G \) be a generic filter, and suppose \( \text{val}(\tau_1) \subseteq \text{val}(\tau_2) \); we want to show that some \( p \in G \) forces \( \tau_1 \sqsubseteq \tau_2 \). Let \( D \) be the set of \( r \in P \) such that

\[
(\ddagger) \text{ there exists } (\pi_1, s_1) \in \tau_1 \text{ with } s_1 \geq r \text{ and such that for any } (\pi_2, s_2) \in \tau_2 \text{ and any } q \leq s_2 \text{ which forces } \pi_1 = \pi_2, \text{ } r \text{ and } q \text{ are incompatible.}
\]

The induction hypothesis for (ii) implies that in the case that \( \phi \) is \( x_1 \subseteq x_2 \), the forcing relation for \( P \)-names of name rank less than \( \alpha \) can be determined in \( M \). Using the fact that \( x_1 = x_2 \) if and only if \( x_1 \sqsubseteq x_2 \), we see that the condition that \( q \) forces \( \pi_1 = \pi_2 \) in \( (\dagger) \) is determined in \( M \), and it follows that \( D \in M \). Then since \( G \) is generic, either some \( r \in D \) belongs to \( G \) or else there is an element of \( G \) none of whose extensions lies in \( D \). We claim that the first case cannot obtain. Suppose to the contrary that some \( r \in G \) satisfies \( (\ddagger) \) and let \( (\pi_1, s_1) \in \tau_1 \) verify this. Since \( r \in G \) and \( r \leq s_1 \), it follows that \( \text{val}(\pi_1) \in \text{val}(\tau_1) \subseteq \text{val}(\tau_2) \), so there must exist \( (\pi_2, s_2) \in \tau_2 \) such that \( s_2 \in G \) and \( \text{val}(\pi_1) = \text{val}(\pi_2) \). But since \( \tau_1 \) and \( \tau_2 \) are both \( P \)-names of name rank less than \( \alpha \), the induction hypothesis for (i) yields that some \( p \in G \) forces \( \pi_1 = \pi_2 \). (Some \( p_1 \in G \) forces \( \pi_1 \sqsubseteq \pi_2 \) and some \( p_2 \in G \) forces \( \pi_2 \sqsubseteq \pi_1 \); find \( p \in G \) less than both \( p_1 \) and \( p_2 \).) Since \( G \) is a filter we can find \( q \in G \) which is less than both \( p \) and \( s_2 \), and then \( q \) forces \( \pi_1 = \pi_2 \), but \( q \) is compatible with \( r \) since both lie in \( G \). This contradicts \( (\ddagger) \), so the claim is proven.

We now know that there exists \( p \in G \) such that every \( r \leq p \) fails to satisfy \( (\ddagger) \). We will show that \( p \) forces \( \tau_1 \sqsubseteq \tau_2 \). Let \( G' \) be any generic filter that contains \( p \) and let \( (\pi_1, s_1) \) be any element of \( \tau_1 \) such that \( s_1 \in G' \). Since \( G' \) is a filter there exists \( r \in G' \) such that \( r \leq p \) and \( r \leq s_1 \); by the failure of \( (\ddagger) \), the set of \( q \in P \) that force \( \pi_1 = \pi_2 \) for some \( (\pi_2, s_2) \in \tau_2 \) with \( s_2 \geq r \) is dense below \( r \). Since \( G' \) is generic it follows that \( G' \) must contain some such \( q \), and therefore \( \text{val}_{G'}(\pi_1) = \text{val}_{G'}(\pi_2) = \text{val}_{G'}(\tau_2) \). Since \( \text{val}_{G'}(\pi_1) \) was an arbitrary element of \( \text{val}_{G'}(\tau_1) \), we have shown that \( \text{val}_{G'}(\tau_1) \subseteq \text{val}_{G'}(\tau_2) \). We conclude that \( p \) forces \( \tau_1 \sqsubseteq \tau_2 \), which completes the proof of (i) in the case that \( \phi \) is \( x_1 \subseteq x_2 \).

To prove (ii), we must show that \( p \) forces \( \tau_1 \sqsubseteq \tau_2 \) if and only if \( (\ddagger) \) holds. The reverse direction is an exercise. For the forward direction, suppose \( p \) forces \( \tau_1 \sqsubseteq \tau_2 \), fix \( (\pi_1, s_1) \in \tau_1 \), and suppose \( r \leq p \) and \( r \leq s_1 \). Let \( G' \) be any generic filter that contains \( r \). Then \( \text{val}_{G'}(\tau_1) \subseteq \text{val}_{G'}(\tau_2) \) since \( r \leq p \), so \( \text{val}_{G'}(\tau_1) \) must equal \( \text{val}_{G'}(\tau_2) \) for some \( P \)-name \( \pi_2 \) such that \( (\pi_2, s_2) \in \tau_2 \) and \( s_2 \in G' \). The induction hypothesis for (i) then implies that there exists \( q \in G' \) which forces \( \pi_1 = \pi_2 \). (Some \( q_1 \) forces \( \pi_1 \sqsubseteq \pi_2 \) and some \( q_2 \) forces \( \pi_2 \sqsubseteq \pi_1 \); find \( q \in G' \) less than both \( q_1 \) and \( q_2 \).) Since \( r, s_2 \in G' \), we may take \( q \) less than both \( r \) and \( s_2 \), which verifies \( (\ddagger) \). This completes the proof of (ii) in the case that \( \phi \) is \( x_1 \subseteq x_2 \).

We have proven the theorem in the case that \( \phi \) is \( x_1 \subseteq x_2 \). This easily implies the result in the case that \( \phi \) is \( x_1 = x_2 \). The remainder of the proof involves proving versions of (i) and (ii) first when \( \phi \) is the atomic formula \( x_1 = x_2 \), and then inductively for formulas \( \phi \) of greater complexity. We omit details; the case when \( \phi \) is \( x_1 = x_2 \) is by far the most difficult.

For any formulas \( \phi \) and \( \psi \) with free variables among \( x_1, \ldots, x_n \) the following is provable in \( \text{ZFC}^* \).

**Corollary 7.3.** Let \( \tau_1, \ldots, \tau_n \) be \( P \)-names.

(a) The set of \( p \) in \( P \) which either force \( \phi(\tau_1, \ldots, \tau_n) \) or \( \neg \phi(\tau_1, \ldots, \tau_n) \) is dense.

(b) \( p \models \neg \phi(\tau_1, \ldots, \tau_n) \) if and only if no \( q \leq p \) forces \( \phi(\tau_1, \ldots, \tau_n) \).

(c) \( p \models (\phi \land \psi)(\tau_1, \ldots, \tau_n) \) if and only if \( p \models \phi(\tau_1, \ldots, \tau_n) \) and \( p \models \psi(\tau_1, \ldots, \tau_n) \).

(d) \( p \models (\forall x)\phi(x, \tau_2, \ldots, \tau_n) \) if and only if \( p \models \phi(\sigma, \tau_2, \ldots, \tau_n) \) for every \( P \)-name \( \sigma \).
Proof. For (a), let \( q \in P \) and find a generic filter \( G \) that contains \( q \). Then either

\[
M[G] \models \phi(\text{val}(\tau_1), \ldots, \text{val}(\tau_n)) \quad \text{or} \quad M[G] \models \neg\phi(\text{val}(\tau_1), \ldots, \text{val}(\tau_n)),
\]

so by Theorem 7.2 (a) there exists \( r \in G \) which forces either \( \phi(\tau_1, \ldots, \tau_n) \) or \( \neg\phi(\tau_1, \ldots, \tau_n) \). Since \( G \) is a filter there exists \( p \in G \) such that \( p \leq q \) and \( p \leq r \); thus there is an extension of \( q \) that forces one of the two statements, which verifies density. The remaining parts are left as exercises.

Exercises

(a) In the proof of Theorem 7.2, show that (†) implies \( p \models \tau_1 \subseteq \tau_2 \).
(b) Prove Corollary 7.3 (b), (c), and (d).

8. \( M[G] \) models ZFC

We are now in a position to check that the remaining axioms of ZFC hold in \( M[G] \). Recall that we have already verified extensionality, pairing, infinity, and foundation (Proposition 6.7). For any formula \( \phi \) the following is a theorem of ZFC*.

**Theorem 8.1.** Let \( P \) be a notion of forcing and let \( G \) be a generic filter of \( P \). Then the axioms of union, power set, and choice are true in \( M[G] \), as are the instances of separation and replacement involving the formula \( \phi \).

**Proof.** Rather than verify all of the axioms we choose two representative cases: separation and power set. For the axiom of separation, let \( \sigma \) and \( \tau_1, \ldots, \tau_n \) be \( P \)-names; we need to show that

\[
S = \{ a \in \text{val}(\sigma) : M[G] \models \phi(a, \text{val}(\tau_1), \ldots, \text{val}(\tau_n)) \}
\]

is in \( M[G] \). We do this by exhibiting the \( P \)-name

\[
\rho = \{ (\pi, p) \in \text{dom}(\sigma) \times P : p \models \"\pi \in \sigma \text{ and } \phi(\pi, \tau_1, \ldots, \tau_n)\" \}.
\]

This is a legitimate \( P \)-name; specifically, it belongs to \( M \) because the forcing relation is determined within \( M \) (Theorem 7.2 (b)).

We will show that \( \text{val}(\rho) = S \). First, let \( a \) be an arbitrary element of \( \text{val}(\rho) \), so that there exists \( (\pi, p) \in \rho \) such that \( p \in G \) and \( a = \text{val}(\pi) \). By the definition of \( \rho \) we then have that \( a = \text{val}(\pi) \in \text{val}(\sigma) \) and \( M[G] \models \phi(\text{val}(\pi), \text{val}(\tau_1), \ldots, \text{val}(\tau_n)) \), and this immediately yields \( a \in S \). For the reverse direction, let \( a \in \text{val}(\sigma) \) and suppose \( \phi(a, \text{val}(\tau_1), \ldots, \text{val}(\tau_n)) \) is true in \( M[G] \). Then \( a = \text{val}(\pi) \) for some \( \pi \in \text{dom}(\sigma) \). By Theorem 7.2 (a), there exists \( p \in G \) which forces \( \"\pi \in \sigma \text{ and } \phi(\pi, \tau_1, \ldots, \tau_n)\" \), so \( (\pi, p) \in \rho \) and hence \( a = \text{val}(\pi) \in \text{val}(\rho) \). This completes the proof of separation.

For the power set axiom, let \( \sigma \) be any \( P \)-name and define

\[
\rho = \{ (\tau, 1_p) : \tau \in P(\text{dom}(\sigma) \times P)^M \}
\]

(i.e., \( \tau \) ranges over all subsets of \( \text{dom}(\sigma) \times P \) that belong to \( M \)). We will show that every subset of \( \text{val}(\sigma) \) in \( M[G] \) belongs to \( \text{val}(\rho) \). This is enough, since \( \text{val}(\rho) \in M[G] \) and an appropriate instance of separation will then show \( P(\text{val}(\sigma))^M[G] \subseteq M[G] \). To prove this let \( \mu \) be a \( P \)-name such that \( \text{val}(\mu) \subseteq \text{val}(\sigma) \). Define

\[
\tau = \{ (\pi, p) : \pi \in \text{dom}(\sigma) \text{ and } p \models \"\pi \in \mu\" \}.
\]

It is clear that \( (\tau, 1_p) \in \rho \), so that \( \text{val}(\tau) \in \text{val}(\rho) \). Finally, we check that \( \text{val}(\mu) = \text{val}(\tau) \). In one direction, any element of \( \text{val}(\mu) \) is of the form \( \text{val}(\pi) \) for some \( \pi \in \text{dom}(\sigma) \). Since \( \text{val}(\pi) \) is in \( \text{val}(\mu) \) some \( p \in G \) forces \( \pi \in \mu \), so that \( (\pi, p) \in \tau \) and hence \( \text{val}(\pi) \in \text{val}(\tau) \). In the reverse direction, any element of \( \text{val}(\tau) \) is of the
form \( \text{val}(\pi) \) such that \( \langle \pi, p \rangle \in \tau \) for some \( p \in G \) with \( p \not\models \pi \in \mu \), and this implies that \( \text{val}(\pi) \in \text{val}(\mu) \). This completes the proof that \( \text{val}(\mu) = \text{val}(\tau) \).

The preceding result motivates the following definition scheme. Let \( \phi \) be a formula with free variables among \( x_1, \ldots, x_n \).

**Definition 8.2.** \( \phi \) is **absolute** if for any notion of forcing \( P \) and any generic filter \( G \) of \( P \), we have

\[
\mathcal{M} \models \phi(u_1, \ldots, u_n) \quad \text{if and only if} \quad \mathcal{M}[G] \models \phi(u_1, \ldots, u_n)
\]

for any \( u_1, \ldots, u_n \in \mathcal{M} \). Also, recalling the caveat given after Definition 4.1, we say that (the standard definition of) a set \( S \) is **absolute** if \( S^\mathcal{M} = S^{\mathcal{M}[G]} \) for any notion of forcing \( P \) and any generic filter \( G \) of \( P \).

For example, Proposition 6.7 and Theorem 8.1 show that every axiom of ZFC is absolute. Also, the formula “\( x \) is an ordinal” is absolute, as is \( \aleph_0 \). But we will see that “\( x \) is a cardinal” and \( \aleph_1 \) are not absolute — for some notions of forcing, the ordinal \( \aleph_1^\mathcal{M} \) becomes countable in \( \mathcal{M}[G] \).

**Exercises**

(a) Prove that the union axiom holds in \( \mathcal{M}[G] \), for any notion of forcing \( P \) and any generic filter \( G \) of \( P \).

**9. Forcing CH**

In this section we will consider the following notion of forcing \( P \). The elements of \( P \) are all the functions \( f \) in \( \mathcal{M} \) such that \( \mathcal{M} \models \text{“} f \text{ is a bijection between countable subsets of } \mathcal{P}(\mathbb{N}) \text{ and } \aleph_1 \text{”} \). That is, \( f \) is a bijection in \( \mathcal{M} \) between subsets of \( \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^\mathcal{M} \), which are countable according to \( \mathcal{M} \). (Of course, since \( \mathcal{M} \) is countable both \( \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^\mathcal{M} \) are actually themselves countable. But \( \mathcal{M} \models \text{“} \mathcal{P}(\mathbb{N}) \text{ and } \aleph_1 \text{ are uncountable”} \)) We call elements of \( P \) countable partial bijections between \( \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^\mathcal{M} \).

We order \( P \) by setting \( f \leq g \) if \( \text{dom}(g) \subseteq \text{dom}(f) \) and \( f|_{\text{dom}(g)} = g \). That is, \( f \) extends \( g \) as an element of \( P \) if and only if \( f \) extends \( g \) as a function.

We will show that the continuum hypothesis is true in \( \mathcal{M}[G] \), for any generic filter \( G \) of \( P \). The idea is that elements of \( P \) give us partial information on how to construct a bijection between \( \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^\mathcal{M} \). When we pass to \( \mathcal{M}[G] \), it will be easy to see that an actual bijection between them has been introduced. The more subtle point is that we must also verify that \( \mathcal{P}(\mathbb{N})^{\mathcal{M}[G]} = \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^{\mathcal{M}[G]} = \aleph_1^\mathcal{M} \); if passing to \( \mathcal{M}[G] \) introduces new sets of natural numbers, for example, then merely having a bijection between the sets that were \( \mathcal{P}(\mathbb{N}) \) and \( \aleph_1 \) in \( \mathcal{M} \) would not verify the continuum hypothesis in \( \mathcal{M}[G] \). The key lemma is the following.

**Definition 9.1.** A preordered set \( P \) is **\( \omega \)-closed** if every decreasing sequence \( a_1 > a_2 > \cdots \) in \( P \) has a lower bound in \( P \).

**Lemma 9.2.** Let \( P \) be any notion of forcing, let \( G \) be a generic filter of \( P \), and suppose \( \mathcal{M} \models \text{“} P \text{ is } \omega \text{-closed”} \). Also let \( A \in \mathcal{M} \). Then any function from \( \mathcal{N} \) to \( A \) in \( \mathcal{M}[G] \) is already in \( \mathcal{M} \).

*Proof.* Suppose there is a function \( f : \mathcal{N} \to A \) that is in \( \mathcal{M}[G] \) but not in \( \mathcal{M} \). Let \( \tau \) be a name for \( f \); by Theorem 7.2 (a), some \( p \in G \) forces the statement “\( \tau \) is a function from \( \mathcal{N} \) to \( A \)”. Let \( X \) be the set of functions from \( \mathcal{N} \) to \( A \) in \( \mathcal{M} \). Then \( f \notin X \), so again by Theorem 7.2 (b) some \( q \in G \) forces \( \neg(\tau \in X) \). We may assume \( q \leq p \).

Define

\[
S = \{ \langle r, n, a \rangle : r \in P, n \in \mathcal{N}, a \in A, \text{ and } r \not\models \langle \bar{n}, \bar{a} \rangle \in \tau \}.
\]

16
By Theorem 7.2 (b) the set \( S \) belongs to \( \mathcal{M} \). We claim that for any \( n \in \mathbb{N} \) the set of \( r \in P \) such that \( \langle r, n, a \rangle \in S \) for some \( a \) is dense below \( p \). To see this, let \( r' \leq p \) and let \( G' \) be a generic filter that contains \( r' \). Since \( r' \leq p \),
\[
\mathcal{M}[G'] \models \text{"val}_{G'}(\tau) \text{ is a function from } \mathbb{N} \text{ to } A".
\]
Therefore
\[
\mathcal{M}[G'] \models \text{"}(n, a) \in \text{val}_{G'}(\tau)"
\]
for some \( a \in A \), and hence some \( r \in G' \) forces \( \langle n, a \rangle \in \tau \). Since \( r' \in G' \) we may assume that \( r \leq r' \), so the claim is proven.

Now, working in \( \mathcal{M} \), choose a sequence \( (p_n) \) in \( P \) and a sequence \( (a_n) \) in \( A \) such that \( q \geq p_0 \geq p_1 \geq \cdots \) and \( p_n \) forces \( \langle n, a_n \rangle \in \tau \). We can do this by the claim. Finally, since \( P \) is \( \omega \)-closed we can find \( p' \in P \) less than the entire sequence \( (p_n) \). This is a contradiction, because \( p' \) forces both \( \langle n, a_n \rangle \in \tau \) for all \( n \) (since it lies below every \( p_n \)) and \( \neg(\tau \in X) \) (since it lies below \( q \)), yet the function \( n \mapsto a_n \) evidently is in \( \mathcal{M} \) (we already constructed the sequence \( (a_n) \) in \( \mathcal{M} \)) and hence it is in \( X \). This proves the lemma.

**Theorem 9.3.** Let \( P \) be the notion of forcing defined in \( \mathcal{M} \) as the set of all countable partial bijections between \( \mathcal{P}(\mathbb{N}) \) and \( \aleph_1 \), ordered by reverse inclusion. Then the continuum hypothesis holds in \( \mathcal{M}[G] \), for any generic filter \( G \) of \( P \).

**Proof.** Let \( G \) be a generic filter of \( P \). First we show that \( \mathcal{P}(\mathbb{N})^{\mathcal{M}[G]} = \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^{\mathcal{M}[G]} = \aleph_1^\mathcal{M} \). The first statement is equivalent to saying that passing from \( \mathcal{M} \) to \( \mathcal{M}[G] \) does not introduce any new functions from \( \mathbb{N} \) to \( \{0, 1\} \), and the second statement is equivalent to saying that passing from \( \mathcal{M} \) to \( \mathcal{M}[G] \) does not introduce a surjection from \( \mathbb{N} \) (which is absolute) onto \( \aleph_1^\mathcal{M} \). Both assertions follow from the lemma, provided we can show that \( \neg \text{"}P \text{ is } \omega \)-closed \text{"} \) is true in \( \mathcal{M} \). But this is trivial: given any decreasing sequence of functions in \( P \) that belongs to \( \mathcal{M} \), their union is a function in \( \mathcal{M} \) which lies below the entire sequence.

Now we must show that \( \mathcal{M}[G] \) contains a bijection between \( \mathcal{P}(\mathbb{N})^{\mathcal{M}[G]} = \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^{\mathcal{M}[G]} = \aleph_1^\mathcal{M} \). By Proposition 6.6, \( G \in \mathcal{M}[G] \). The elements of \( G \) are a directed set of partial bijections, so the union of all functions in \( G \) is a bijection between a subset of \( \mathcal{P}(\mathbb{N})^\mathcal{M} \) and a subset of \( \aleph_1^\mathcal{M} \). Let \( f \) be this union; it belongs to \( \mathcal{M}[G] \) since the latter satisfies the union axiom. Moreover, for each \( x \in \mathcal{P}(\mathbb{N})^\mathcal{M} \) the set of functions in \( P \) whose domain contains \( x \) is dense, and for each \( y \in \aleph_1^\mathcal{M} \) the set of functions in \( P \) whose image contains \( y \) is dense (exercise). Since both of these sets lie in \( \mathcal{M} \) and \( G \) is generic, it follows that \( f \) is a bijection between \( \mathcal{P}(\mathbb{N})^\mathcal{M} \) and \( \aleph_1^\mathcal{M} \). Thus the continuum hypothesis is true in \( \mathcal{M}[G] \).

**Exercises**

(a) Let \( \tau \) and \( \sigma \) be \( \mathcal{P} \)-names. Find a \( \mathcal{P} \)-name \( \pi \) such that \( \text{val}_G(\pi) = \langle \text{val}_G(\tau), \text{val}_G(\sigma) \rangle \) for any generic filter \( G \). (By definition, \( \langle x, y \rangle = \{\{x\}, \{x, y\}\} \) for any sets \( x \) and \( y \).)

(b) Let \( P \) be the notion of forcing used in Theorem 9.3. Prove that for each \( x \in \mathcal{P}(\mathbb{N})^\mathcal{M} \) the set of \( f \in P \) whose domain contains \( x \) is dense, and for each \( y \in \aleph_1^\mathcal{M} \) the set of \( f \in P \) whose image contains \( y \) is dense.

(c) Exhibit a notion of forcing \( P \) such that for any generic filter \( G \) of \( P \) we have \( \aleph_1^\mathcal{M} = \aleph_1^{\mathcal{M}[G]} \), but \( \aleph_2^\mathcal{M} < \aleph_2^{\mathcal{M}[G]} \).

**10. Forcing \neg \text{CH}**

In the last section we had to force \( 2^{\aleph_0} \), which could have been larger than \( \aleph_1 \) in \( \mathcal{M} \), to equal \( \aleph_1 \) in \( \mathcal{M}[G] \). This was accomplished using a notion of forcing which told us how to build a bijection between \( \mathcal{P}(\mathbb{N}) \) and \( \aleph_1 \). In this section we want to force \( 2^{\aleph_0} > \aleph_1 \), and we will do this using a notion of forcing which tells us how to build a set of \( \aleph_2 \) distinct functions from \( \mathbb{N} \) into \( \{0, 1\} \).

The appropriate notion of forcing \( P \) is the set of all functions from finite subsets of \( \mathbb{N} \times \aleph_2^\mathcal{M} \) into \( \{0, 1\} \). We call elements of \( P \) **finite partial functions** from \( \mathbb{N} \times \aleph_2^\mathcal{M} \) into \( \{0, 1\} \). Note that we do not have to say “functions in \( \mathcal{M} \)” because for any \( A, B \in \mathcal{M} \), any function from a finite subset of \( A \) into \( B \) can be explicitly listed and hence belongs to \( \mathcal{M} \). We order \( P \) by setting \( f \leq g \) if \( \text{dom}(g) \subseteq \text{dom}(f) \) and \( f|_{\text{dom}(g)} = g \). Again,
If every down-antichain in a notion of forcing $P$ is a set $A \subset P$ such that any two distinct elements of $A$ are incompatible, $P$ is c.c.c. if every down-antichain in $P$ is countable.

Definition 10.1. A down-antichain in a notion of forcing $P$ is a set $A \subset P$ such that any two distinct elements of $A$ are incompatible. $P$ is c.c.c. if every down-antichain in $P$ is countable.

Definition 10.2. Let $P$ be a notion of forcing. We say that $P$ preserves cardinals if for any generic filter $G$ of $P$ and any ordinal $\alpha \in M,$

$$M \models \text{“}\alpha \text{ is a cardinal”} \iff M[G] \models \text{“}\alpha \text{ is a cardinal”}.$$  

Note that the reverse implication is automatic: if $\alpha$ is not a cardinal in $M,$ then there is a bijection in $M$ between $\alpha$ and some smaller ordinal. This bijection will still exist in $M[G],$ so $\alpha$ cannot become a cardinal there. Thus, to say that $P$ preserves cardinals is to say that the cardinals in $M[G]$ are the same as the cardinals in $M.$ (We already saw that $M$ and $M[G]$ have the same ordinals in § 6, Exercise (d).)

We will now show that every c.c.c. notion of forcing preserves cardinals.

Lemma 10.3. Let $P$ be a notion of forcing such that $M \models \text{“}P \text{ is c.c.c.”}$ and let $G$ be a generic filter. Suppose $f : A \to B$ is a function in $M[G]$ with $A, B \in M.$ Then there is a map $F : A \to \mathcal{P}(B)$ in $M$ such that for each $a \in A$ we have $f(a) \in F(a)$ and $M \models \text{“}F(a) \text{ is countable”}.$

Proof. Let $\tau$ be a $P$-name for $f$ and let $p \in G$ force “$\tau$ is a function from $\check{A}$ to $\check{B}$.” For $a \in A$ define

$$F(a) = \{ b \in B : \text{ some } q \leq p \text{ forces } \langle \check{a}, \check{b} \rangle \in \tau \}.$$  

Then $F$ is in $M$ and since some $q \in G,$ and hence some $q \leq p,$ must force $\langle \check{a}, \check{b} \rangle \in \tau$ with $b = f(a),$ we have $f(a) \in F(a).$ We need only show that $M \models \text{“}F(a) \text{ is countable”}.$

To see this, fix $a \in A$ and, working in $M,$ for each $b \in F(a)$ find $q_b \leq p$ such that $q_b \forces \langle \check{a}, \check{b} \rangle \in \tau.$ Then the $q_b$ are incompatible since they force different values of $\text{val}(\tau)(a)$ (and they all lie below $p,$ which forces $\text{val}(\tau)$ to be a function). Since “$P$ is c.c.c.” is true in $M,$ “$F(a)$ is countable” must also be true in $M.$

Theorem 10.4. Let $P$ be a notion of forcing such that $M \models \text{“}P \text{ is c.c.c.”}$ Then $P$ preserves cardinals.

Proof. Let $G$ be a generic filter of $P$ and suppose $\alpha \in M$ is a cardinal in $M$ but not in $M[G].$ Then there is a smaller cardinal $\beta$ in $M$ and a function $f$ in $M[G]$ from $\beta$ onto $\alpha.$ By the lemma there is then a map $F : \beta \to \mathcal{P}(\alpha)$ in $M$ such that for each $x \in \beta$ we have $f(x) \in F(x)$ and $M \models \text{“}F(x) \text{ is countable”}.$ But then

$$M \models \text{“card}(\bigcup_{x \in \beta} F(x)) \leq \aleph_0 \cdot \beta = \beta$$

(it is clear that $\beta$ cannot be finite). However, $f$ is surjective and its image is contained in $\bigcup_{x \in \beta} F(x),$ so that the latter must equal $\alpha.$ We have shown that $M \models \text{“card}(\alpha) \leq \beta,$” a contradiction.

The main remaining step is to show that the notion of forcing described at the beginning of this section is c.c.c. in $M.$ We do this using the following combinatorial lemma, the $\Delta$-systems lemma. This is provable in ZFC.

Lemma 10.5. Let $A$ be an uncountable family of finite sets. Then there is an uncountable subfamily $B \subset A$ and a set $r$ such that $a \cap b = r$ for any distinct $a, b \in B.$
Proof. For each $n \in \mathbb{N}$ let $A_n = \{a \in A : \text{card}(a) = n\}$. Then some $A_n$ is uncountable; fix such a value of $n$. Let $r$ be a maximal set with the property that $r \subseteq a$ for uncountably many $a \in A_n$, and let $A'_n = \{a \in A_n : r \subseteq a\}$. Then $A'_n$ is uncountable and any $x \notin r$ belongs to only countably many $a \in A'_n$. Finally, by Zorn’s lemma let $B$ be a maximal subset of $A'_n$ with the property that $a \cap b = r$ for any distinct $a, b \in B$. If $B$ were countable then $\bigcup_{a \in B} a$ would be countable and each $x \in (\bigcup_{a \in B} a) - r$ would belong to only countably many $a \in A_n$, so there would exist an $a \in A'_n$ whose intersection with every $b \in B$ is $r$, contradicting maximality of $B$. Thus $B$ must be uncountable.

Theorem 10.6. Let $P$ be the notion of forcing consisting of all finite partial functions from $\mathbb{N} \times 2^\mathbb{N}$ into $\{0, 1\}$, ordered by reverse inclusion. Then the continuum hypothesis fails in $M[G]$, for any generic filter $G$ of $P$.

Proof. Let $G$ be a generic filter of $P$. Working in $M$, we show that $P$ is c.c.c. Let $A$ be an uncountable subset of $P$. Applying Lemma 10.5 (which is provable in ZFC, hence true in $M$) to the domains of the functions in $A$, we infer that there is an uncountable subset $B$ of $A$ and a (finite) set $r \subseteq \mathbb{N} \times 2^\mathbb{N}$ such that $\text{dom}(f) \cap \text{dom}(g) = r$ for any distinct $f, g \in B$. But there are only finitely many (specifically, $2^{\text{card}(r)}$) possible choices for $f|_r$, so there must be some distinct $f, g \in B$ with $f|_r = g|_r$. Since the union of this $f$ and $g$ is a finite partial function, they are compatible. So, working in $M$, we have shown that any uncountable subset of $P$ contains compatible functions, and hence that $P$ is c.c.c.

It now follows from Theorem 10.4 that $\mathbb{N}^{\mathbb{N}}_2 = \aleph_2$. By Proposition 6.6, $G \in M[G]$. Any two elements of $G$ are compatible partial functions from $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}_2$ into $\{0, 1\}$, so the union of all functions in $G$ is a function from a subset of $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}_2$ into $\{0, 1\}$. Let $F$ be this union; it belongs to $M[G]$. Moreover, for each $(n, \alpha) \in \mathbb{N} \times \mathbb{N}^{\mathbb{N}}_2$ the set of finite partial functions whose domain contains $(n, \alpha)$ is dense and lies in $M$, so $G$ must intersect this set and hence $F$ is a function from $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}_2$ into $\{0, 1\}$.

Working in $M[G]$, for each $\alpha < \aleph_2$ let

$$S_\alpha = \{n \in \mathbb{N} : F(n, \alpha) = 1\}.$$

For any distinct $\alpha, \beta < \aleph_2$ the set

$$\{f \in P : (\exists n \in \mathbb{N})(n, \alpha), (n, \beta) \in \text{dom}(f) \text{ and } f(n, \alpha) \neq f(n, \beta)\}$$

is dense and belongs to $M$. Since $G$ is generic, this shows that $S_\alpha \neq S_\beta$. Thus

$$M[G] \models \{S_\alpha : \alpha < \aleph_2^M\} \text{ is a family of distinct subsets of } \mathbb{N} \text{ of cardinality } \aleph_2,$$

which shows that the continuum hypothesis fails in $M[G].$ $
$

Exercises

(a) For any $A, B \in M$ prove that (1) the set of all finite subsets of $A$ and (2) the set of all functions from a finite subset of $A$ into $B$ are absolute.

(b) Exhibit a notion of forcing $P$ such that for any generic filter $G$, $M[G] \models \"\aleph_1^M \text{ is countable}\"$.

(c) Prove that it is relatively consistent with ZFC that $2^{\aleph_0} \geq \aleph_1$.

11. Application: families of analytic functions

We work in ZFC. The following theorem is due to Paul Erdős.

Theorem 11.1. The continuum hypothesis is true if and only if there is an uncountable family of analytic functions $f_\alpha$ on the complex plane such that for each $z \in \mathbb{C}$ the set of values $\{f_\alpha(z)\}$ is countable.

Proof. $(\Rightarrow)$ Suppose CH fails. Let $\{f_\alpha : \alpha < \aleph_1\}$ be an uncountable family of distinct analytic functions on the complex plane; we will find a point in $\mathbb{C}$ at which the family takes on uncountably many values. (It is sufficient to consider the case that the family has cardinality $\aleph_1$ since we can always discard extra functions.)
We invoke a theorem from complex analysis which states that if \( f \) and \( g \) are analytic functions and the set of points at which they agree has a cluster point, then \( f = g \). It follows that two distinct analytic functions can agree on at most countably many points in \( C \). (If they agreed on uncountably many points, then for some \( n \) the compact disk \( \{ |z| \leq n \} \) would contain infinitely many points of agreement, and there would be a cluster point in this disk.)

For each distinct \( \alpha, \beta \in \mathbb{N}_1 \), let
\[
S(\alpha, \beta) = \{ z \in C : f_\alpha(z) = f_\beta(z) \}.
\]

Then \( \bigcup_{\alpha \neq \beta} S(\alpha, \beta) \) is a union of \( \aleph_1^2 = \aleph_1 \) countable sets and hence has size at most \( \aleph_1 \). Since \( \text{card}(C) = 2^{\aleph_0} \) and we are assuming \( 2^{\aleph_0} > \aleph_1 \), it follows that there exists a point \( z_0 \in C \) that does not belong to any \( S(\alpha, \beta) \). This means that \( \alpha \neq \beta \) implies \( f_\alpha(z_0) \neq f_\beta(z_0) \), so that the family of functions \( \{ f_\alpha \} \) takes on uncountably many values at the point \( z_0 \).

\((\Rightarrow)\) Suppose \( \text{CH} \) holds. Let \( S \) be the set of complex numbers \( a+bi \) with \( a \) and \( b \) both rational. Since \( 2^{\aleph_0} = \aleph_1 \), we can enumerate the complex plane as \( C = \{ z_\alpha : \alpha < \aleph_1 \} \). We will construct a family \( \{ f_\beta : \beta < \aleph_1 \} \) of distinct analytic functions such that \( f_\beta(z_\alpha) \in S \) for all \( \beta > \alpha \). This implies that the set of values of the \( f_\beta \) on each \( z_\alpha \) is countable, since (fixing \( \alpha \) \( \{ f_\beta(z_\alpha) : \beta \leq \alpha \} \) is trivially countable and \( \{ f_\beta(z_\alpha) : \beta > \alpha \} \subseteq S \) is also countable.

We construct the \( f_\beta \) by transfinite recursion. Suppose \( f_\beta \) has been defined for all \( \beta < \gamma \). The set \( \{ f_\beta : \beta < \gamma \} \) is countable, so we can reorder it as \( \{ g_\beta : \beta < \gamma \} \). Similarly, we can reorder \( \{ z_\alpha : \alpha < \gamma \} \) as \( \{ w_\alpha : \alpha < \gamma \} \).

We will construct \( f_\gamma \) so as to satisfy

(i) \( f_\gamma(w_\alpha) \in S \) for all \( \alpha \) and

(ii) \( f_\gamma(w_\alpha) \neq g_\beta(w_\alpha) \) for all \( \alpha < \beta \).

It will follow from (i) that \( f_\gamma(z_\alpha) \in S \) for all \( \alpha < \gamma \), and from (ii) that \( f_\gamma \neq f_\beta \) for all \( \beta < \gamma \).

We let \( f_\gamma \) be a function of the form
\[
f_\gamma(z) = \epsilon_0 + \sum_{n=1}^{\infty} \epsilon_n \prod_{i=0}^{n-1} (z - w_i)
\]
where \( \epsilon_n \) is chosen small enough so that \( |\epsilon_n \prod_{i=0}^{n-1} (z - w_i)| \leq 2^{-n} \) on \( \{ |z| \leq n \} \). This implies that the sum converges uniformly on compact sets, so that it defines an analytic function. We can choose the \( \epsilon_n \) sequentially, and arrange both conditions (i) and (ii) for \( w_\alpha \) when choosing \( \epsilon_n \) since future terms of the sum vanish on \( w_\alpha \).

\( \blacksquare \)

**Exercises**

(a) Let \( \{ f_\alpha : \alpha \in \mathbb{N} \} \) be infinitely many distinct analytic functions on \( C \). Prove that there exists \( z \in C \) such that the set of values \( \{ f_\alpha(z) : \alpha \in \mathbb{N} \} \) is infinite.

(b) Prove that there are \( 2^{\aleph_0} \) distinct continuous functions from \( C \) into \([0,1]\) which collectively take at most two values at each point. (Hint: do this first for functions from \( \mathbb{R} \) into \([0,1]\).) Can this be done for infinitely differentiable functions?

(c) Prove that for any uncountable family of complex polynomials, there exists a point in \( C \) at which the family takes on uncountably many values.

12. Application: self-homeomorphisms of $\beta N - N$, I

We work in ZFC. In this section we show that CH implies there are nontrivial homeomorphisms from the topological space $\beta N - N$ onto itself. What we mean by “nontrivial” is explained below. It is also relatively consistent with ZFC that all self-homeomorphisms of $\beta N - N$ are trivial; we will discuss this later.

**Definition 12.1.** A filter over a set $X$ is a family $\mathcal{F}$ of subsets of $X$ which is closed under enlargement ($A \in \mathcal{F}$ and $A \subseteq B$ implies $B \in \mathcal{F}$) and finite intersections ($A, B \in \mathcal{F}$ implies $A \cap B \in \mathcal{F}$). (That is, it is a filter of the poset $\mathcal{P}(X)$ in the sense of Definition 6.1 (c).) An ultrafilter is a maximal proper filter.

We consider ultrafilters over $N$. For any $n \in N$ there is a trivial fixed ultrafilter $U_n = \{ A \subseteq N : n \in A \}$. However, there are other ultrafilters; the cofinite filter $\mathcal{F}_{cof} = \{ A \subseteq N : N - A \text{ is finite} \}$ is a filter, and by Zorn’s lemma, every filter is contained in an ultrafilter, but no ultrafilter containing $\mathcal{F}_{cof}$ can be fixed. An ultrafilter which is not fixed is called free.

**Proposition 12.2.** A filter $\mathcal{F}$ over $N$ is an ultrafilter if and only if for every $A \subseteq N$, either $A \in \mathcal{F}$ or $N - A \in \mathcal{F}$ (but not both).

**Proof.** Exercise.

**Definition 12.3.** The Stone-Čech compactification of $N$, $\beta N$, is the set of all ultrafilters over $N$ with the topology whose basic open sets are, for every $A \subseteq N$, the set $U_A$ of all ultrafilters containing $A$.

We record basic information about $\beta N$ in the next result.

**Proposition 12.4.** The sets $U_A$ form a basis for a topology on $\beta N$. This topology is compact, Hausdorff, and totally disconnected. The map $n \mapsto U_n$ embeds $N$ into $\beta N$ as a dense open set of isolated points.

**Proof.** Exercise.

It follows from Proposition 12.4 that $\beta N - N$ — the subspace of $\beta N$ consisting of all free ultrafilters — is also compact, Hausdorff, and totally disconnected. It has a basis consisting of the sets

$$U_A = U_A \cap (\beta N - N) = \{ \text{free ultrafilters which contain } A \}$$

for all $A \subseteq N$. We now introduce the “obvious” self-homeomorphisms of $\beta N - N$.

**Definition 12.5.** An almost permutation of $N$ is a bijection between two cofinite subsets of $N$.

**Proposition 12.6.** Let $\phi : S \cong T$ be an almost permutation of $N$. For any free ultrafilter $U$ over $N$ define $\tilde{\phi}(U)$ to be

$$\tilde{\phi}(U) = \{ \phi(A \cap S) \cup B : A \in U \text{ and } B \subseteq N - T \}$$

(where $\phi(A \cap S) = \{ \phi(n) : n \in A \cap S \}$). Then $\tilde{\phi}$ is a self-homeomorphism of $\beta N - N$.

**Proof.** If $S = T = N$ the proposition is trivial. We need only consider the case when $S = N$, $T = N - \{0\}$, and $\phi$ is the unilateral shift $\phi(n) = n + 1$; this is sufficient because every almost permutation of $N$ can be expressed as a composition of permutations of $N$ and some power of the unilateral shift or its inverse. (Apply a permutation to map $S$ to $\{j, j+1, \ldots \}$ where $j = \text{card}(N - S)$, then compose with $\phi^{k-j}$ to take this set to $\{k, k+1, \ldots \}$ where $k = \text{card}(N - T)$, and then compose with another permutation to take $\{k, k+1, \ldots \}$ onto $T$ in a way that matches the given almost permutation.)

Suppose now that $\phi$ is the unilateral shift. The verification that $\tilde{\phi}$ is a well-defined bijection of $\beta N - N$ with itself is routine. It is a homeomorphism because it permutes the basic open sets $U_A$. Specifically, $\tilde{\phi}$ takes $U_A$ to $U_{A'}$ where $A' = \{ n + 1 : n \in A \}$. Every basic open set is of the form $U_{A'}$ for some $A$ because in general $U_A = U_B$ provided the symmetric difference of $A$ and $B$ is finite.
We call a self-homeomorphism of $\beta \mathbb{N} - \mathbb{N}$ arising from an almost permutation of $\mathbb{N}$ trivial. We will show that CH implies there are nontrivial self-homeomorphisms of $\beta \mathbb{N} - \mathbb{N}$. This is done using the poset $\mathcal{P}(\mathbb{N})/\text{fin}$ defined as follows.

**Definition 12.7.** Let $\mathcal{P}(\mathbb{N})/\text{fin}$ be the quotient of $\mathcal{P}(\mathbb{N})$ by the equivalence relation that makes two subsets of $\mathbb{N}$ equivalent if their symmetric difference is finite. The natural order relation on $\mathcal{P}(\mathbb{N})/\text{fin}$ is: the class of $A$ less than the class of $B$ if $A$ is essentially contained in $B$, i.e., all but finitely many elements of $A$ are also in $B$.

**Lemma 12.8.** The poset of clopen subsets of $\beta \mathbb{N} - \mathbb{N}$ under containment is order-isomorphic to $\mathcal{P}(\mathbb{N})/\text{fin}$. This induces a 1-1 correspondence between the self-homeomorphisms of $\beta \mathbb{N} - \mathbb{N}$ and the order-automorphisms of $\mathcal{P}(\mathbb{N})/\text{fin}$.

**Proof.** First, we claim that the clopen subsets of $\beta \mathbb{N} - \mathbb{N}$ are precisely the basic open sets $U_A$ for $A \subseteq \mathbb{N}$. It follows from Proposition 12.2 that the complement of $U_A$ is $U_{\mathbb{N} - A}$, so the basic open sets are all clopen. Now any open subset can be expressed as a union of basic open sets, and since $\beta \mathbb{N} - \mathbb{N}$ is compact any closed subset is compact, so any clopen subset is a union of finitely many basic open sets. However, the union $U_{A_1} \cup \cdots \cup U_{A_n}$ equals the single basic open set $U_{A_1 \cup \cdots \cup A_n}$. So every clopen set is a basic open set. This completes the proof of the claim.

If the symmetric difference of $A$ and $B$ is finite then $U_A = U_B$, because any free ultrafilter contains $A$ if and only if it contains $B$. However, if the symmetric difference of $A$ and $B$ is infinite then there is a free ultrafilter that contains one but not the other: say $A - B$ is infinite and extend the filter generated by $A - B$ and the cofinite subsets of $\mathbb{N}$ to an ultrafilter. So the map taking $U_A$ to the class of $A$ is a bijection between the clopen subsets of $\beta \mathbb{N} - \mathbb{N}$ and the elements of $\mathcal{P}(\mathbb{N})/\text{fin}$. We have that $A$ is essentially contained in $B$ if and only if every free ultrafilter that contains $A$ also contains $B$ if and only if $U_A \subseteq U_B$. So the bijection is an order-isomorphism. This proves the first assertion.

It is clear that any self-homeomorphism of $\beta \mathbb{N} - \mathbb{N}$ induces an order-automorphism of the poset of clopen subsets of $\beta \mathbb{N} - \mathbb{N}$. Conversely, every order-automorphism of the poset of clopen subsets permutes the maximal proper filters of this poset. But by compactness of $\beta \mathbb{N} - \mathbb{N}$, the intersection of any proper filter of clopen sets is nonempty, and if $x$ is any point in the intersection then the original filter must be contained in the filter consisting of all clopen sets that contain $x$. This shows that the maximal proper filters are precisely the filters of the form: all clopen sets containing the point $x$, as $x$ ranges over $\beta \mathbb{N} - \mathbb{N}$. We conclude that any order-automorphism of the poset of clopen subsets permutes the points of $\beta \mathbb{N} - \mathbb{N}$, and since this permutation takes basic open sets to basic open sets it is a self-homeomorphism. We have established that any self-homeomorphism of $\beta \mathbb{N} - \mathbb{N}$ induces an order-automorphism of $\mathcal{P}(\mathbb{N})/\text{fin}$, and conversely; finally, it is routine to check that these maps are inverse to each other.

**Lemma 12.9.** Let $(A_n)$, $(B_n)$, and $(C_n)$ be sequences of subsets of $\mathbb{N}$ such that every $A_i$ is essentially contained in every $B_j$, but not vice versa; no $C_k$ is essentially contained in any $A_i$; and no $C_k$ essentially contains any $B_j$. Also suppose that the $A_n$ are directed upward and the $B_n$ are directed downward under almost containment. Then there are two subsets $A$ and $B$ of $\mathbb{N}$ with infinite symmetric difference which essentially contain (but are not essentially contained in) each $A_n$, are essentially contained in (but do not essentially contain) each $B_n$, and neither essentially contain nor are essentially contained in any $C_n$.

**Proof.** We construct sequences

$$S_1 \subseteq S_1' \subset S_2 \subset S_2' \subset \cdots$$

and

$$T_1 \subseteq T_1' \subset T_2 \subset T_2' \subset \cdots$$

such that $S_n \cap T_n = \emptyset$ for all $n$. We think of the elements of $S_n$ as required and the elements of $T_n$ as forbidden. Start with $S_1 = T_1 = \emptyset$. Given $S_n$ and $T_n$, construct $S_n'$ from $S_n$ by adding $A_n$, then subtracting $T_n$, then adding a point in $\mathbb{N} - (A_i \cup T_n)$ for each $1 \leq i \leq n$. Then construct $T_n'$ by adding $\mathbb{N} - B_n$, subtracting $S_n'$, and adding a point in $B_i - S_n'$ for each $1 \leq i \leq n$. Then construct $S_{n+1}$ by adding to $S_n'$
one point in $N - (C_i \cup T'_n)$ for each $1 \leq i \leq n$ such that $S'_n$ is essentially contained in $C_i$, and construct $T_{n+1}$ by adding to $T'_n$ one point in $C_i - S_{n+1}$ for each $1 \leq i \leq n$ such that $N - T'_n$ essentially contains $C_i$. The construction can proceed because we inductively have that $S_n$ has finite symmetric difference with $A_1 \cup \cdots \cup A_n$ and $T_n$ has finite symmetric difference with $N - (B_1 \cap \cdots \cap B_n)$. Finally, let $A = \bigcup S_n$. It is immediate that $A$ essentially contains every $A_n$, and by the construction of $S'_n$ it contains infinitely many points outside of each $A_n$. Since $A$ does not intersect $\bigcup T_n$, it is essentially contained in each $B_n$, and by the construction of $T'_n$ it avoids infinitely many points in each $B_n$. By the construction of $S_n$ and $T_n$ we have that $A$ neither essentially contains nor is essentially contained in any $C_n$. To find a set $B$ with the same properties that essentially contains but is not essentially contained in $A$, add $A$ to the family $\{A_n\}$ and apply the construction again.

**Theorem 12.10.** Assume the continuum hypothesis. Then there exist nontrivial self-homeomorphisms of $\beta N - N$.

**Proof.** By Lemma 12.8, it suffices to find a nontrivial order-automorphism of $\mathcal{P}(N)/\text{fin}$. There are $2^{\aleph_0}$ trivial order-automorphisms; enumerate them as $\{\psi_\alpha : \alpha < \aleph_1\}$. The cardinality of $\mathcal{P}(N)/\text{fin}$ is also $2^{\aleph_0}$, so enumerate its elements as $\{x_\alpha : \alpha < \aleph_1\}$. We recursively construct countable subsets $A_\alpha$ of $\mathcal{P}(N)/\text{fin}$ which are closed under finite unions, finite intersections, and complements, together with injective maps $\phi_\alpha : A_\alpha \to \mathcal{P}(N)/\text{fin}$, such that, with $B_\alpha = \phi_\alpha(A_\alpha)$,

(i) if $\beta \leq \alpha$ then $A_\beta \subseteq A_\alpha$, $B_\beta \subseteq B_\alpha$, and $\phi_\alpha|_{A_\beta} = \phi_\beta$;

(ii) $\phi_\alpha$ preserves finite unions, finite intersections, and complements;

(iii) $\phi_\alpha$ disagrees with $\psi_\alpha$ on $A_\alpha$; and

(iv) $x_\alpha$ is in both $A_\alpha$ and $B_\alpha$.

At stage $\alpha$ of the construction, if $x_\alpha \notin \bigcup_{\beta < \alpha} A_\beta$ then we let $y_\alpha = x_\alpha$; otherwise we choose $y_\alpha$ arbitrarily in the complement of $\bigcup_{\beta < \alpha} A_\beta$. Then we let $A_\alpha$ be generated by $\bigcup_{\beta < \alpha} A_\beta$ and $y_\alpha$ under the operations of union, intersection, and complement, extend the previously defined $\phi_\beta$ to an embedding $\tilde{\phi}_\alpha$ of $A_\alpha$ in $\mathcal{P}(N)/\text{fin}$, and let $B_\alpha = \tilde{\phi}_\alpha(A_\alpha)$. If $B_\alpha$ contains $x_\alpha$ then we let $A_\alpha = A_\alpha$, $B_\alpha = B_\alpha$, and $\phi_\alpha = \tilde{\phi}_\alpha$; otherwise we let $B_\alpha$ be generated by $B_\alpha$ and $x_\alpha$ under the operations of union, intersection, and complement, extend $\tilde{\phi}_\alpha^{-1}$ to $B_\alpha$, and let $A_\alpha$ be the image of $B_\alpha$ under the extension and $\phi_\alpha$ the inverse of the extension.

The point is that there are always at least two ways to define $\tilde{\phi}_\alpha$, hence at most one of them can agree with $\psi_\alpha$, and we can ensure condition (iii) by choosing the other one. To define the extension, partition $\bigcup_{\beta < \alpha} A_\beta$ into those elements which lie below $y_\alpha$, those which lie above $y_\alpha$, and those which are incomparable to $y_\alpha$. This corresponds to a partition of $\bigcup_{\beta < \alpha} B_\beta$, which can be lifted to three countable families of subsets of $N$ that satisfy the hypotheses of Lemma 12.9. That lemma then provides us with two suitable targets for $y_\alpha$; this determines the construction of $\tilde{\phi}_\alpha$, and it is straightforward to check that this does produce a well-defined map with the desired properties.

Finally, we define an order-automorphism $\phi$ of $\mathcal{P}(N)/\text{fin}$ by taking the union of the maps $\phi_\alpha$. It is injective since each $\phi_\alpha$ is injective, it is surjective since for each $\alpha$ its image contains $x_\alpha \in B_\alpha$, and it is an order-isomorphism since each $\phi_\alpha : A_\alpha \cong B_\alpha$ is an order-isomorphism. It disagrees with each $\psi_\alpha$ by construction, so it is a nontrivial order-automorphism.

**Exercises**

(a) Prove Proposition 12.2.

(b) Prove Proposition 12.4. (Hint: for compactness, first look at Exercise (c).)

(c) In the proof of Lemma 12.8 show that $\bar{U}_{A_1} \cup \cdots \cup \bar{U}_{A_n} = \bar{U}_{A_1 \cup \cdots \cup A_n}$.

(d) Prove that any self-homeomorphism of $\beta N$ arises from a permutation of $N$.

**References**

13. Application: pure states on $\mathcal{B}(H)$

We work in ZFC. Let $H$ be a separable infinite-dimensional complex Hilbert space and let $\mathcal{B}(H)$ be the set of all bounded linear operators from $H$ to itself.

**Definition 13.1.** A (concrete) C*-algebra is a norm-closed linear subspace of $\mathcal{B}(H)$ that is stable under adjoints and products (i.e., composition of operators). It is unital if it contains the identity operator on $H$. A state on a unital C*-algebra $\mathcal{A}$ is a bounded linear functional $f : \mathcal{A} \to \mathbb{C}$ such that $\|f\| = f(I) = 1$, where $I$ is the identity operator. It is pure if it cannot be expressed as $f = (f_1 + f_2)/2$ for distinct states $f_1$ and $f_2$.

For example, if $v$ is a unit vector in $H$ then the map $f_v : A \to \langle Av, v \rangle$ is a state on $\mathcal{B}(H)$ because

$$\langle Iv, v \rangle = \langle v, v \rangle = 1$$

(so that $f_v(I) = 1$ and consequently $\|f_v\| \geq 1$) and for any operator $A \in \mathcal{B}(H)$

$$|f_v(A)| = |\langle Av, v \rangle| \leq \|Av\| \|v\| \leq \|A\| \|v\|^2 = \|A\|$$

(so that $\|f_v\| \leq 1$). In fact it is pure, though this is a little harder to show. Any convex combination of states is a state; thus the set of all states is convex, and the pure states are its extreme points.

Let $U$ be an ultrafilter over $\mathbb{N}$ and let $(a_n)$ be a bounded sequence of complex numbers. For each $A \in U$ let $S_A$ be the closure of $\{a_n : n \in A\}$; then each $S_A$ is compact, and they have the finite intersection property because

$$S_{A_1 \cap \cdots \cap A_n} \subseteq S_{A_1} \cap \cdots \cap S_{A_n}.$$ 

So $\bigcap_{A \in U} S_A$ is nonempty. Furthermore, it must consist of a single point because any two distinct points in $\mathbb{C}$ can be separated by a pair of open sets $U$ and $V$; since either $\{n : a_n \in U\}$ or $\{n : a_n \notin U\}$ is in $U$, but not both, some $S_A$ is contained in either the closure of $U$ or the complement of $U$. Thus $\bigcap_{A \in U} S_A = \{a\}$ for some complex number $a$. We write $\lim_{U} a_n = a$. (This construction would work for ultrafilters over any set, a fact we will use in the proof of Lemma 13.4.)

The following theorem is due to Joel Anderson. We omit the proof.

**Theorem 13.2.** Let $(e_n)$ be an orthonormal basis of $H$ and let $U$ be an ultrafilter over $\mathbb{N}$. Then

$$f(A) = \lim_{U} \langle Ae_n, e_n \rangle$$

defines a pure state on $\mathcal{B}(H)$.

The states described in Theorem 13.2 are called diagonalizable, and until recently it was not known whether there are any pure states on $\mathcal{B}(H)$ that are not diagonalizable. Charles Akemann and I recently proved that CH implies there exist non-diagonalizable pure states. The relative consistency with ZFC of the statement “all pure states are diagonalizable” remains open.

We will give the non-diagonalizable construction, leaving out the proof of one key C*-algebraic lemma. An operator in $\mathcal{B}(H)$ is finite rank if its range is finite-dimensional. We omit the proof of the following result.

**Lemma 13.3.** Let $\mathcal{A} \subseteq \mathcal{B}(H)$ be a separable unital C*-algebra which contains all finite rank operators. Let $f$ be a pure state on $\mathcal{A}$ that is zero on all finite rank operators and let $(e_n)$ be an orthonormal basis of $H$. Then there is a subset $S \subseteq \mathbb{N}$ and a pure state $g$ on $\mathcal{B}(H)$ that extends $f$ such that $0 < g(P) < 1$ where $P$ is the operator defined by

$$Pe_n = \begin{cases} e_n & \text{if } n \in S \\ 0 & \text{if } n \notin S. \end{cases}$$
We call the operator $P$ in Lemma 13.3 an orthogonal projection that is diagonalized by $(e_n)$. Observe that for any ultrafilter $\mathcal{U}$ over $\mathbb{N}$ the pure state $A \mapsto \lim_{\mathcal{U}}(Ae_n,e_n)$ takes either the value 1 or the value 0 on $P$, depending on whether $S$ or $\mathbb{N} - S$ is in $\mathcal{U}$.

**Lemma 13.4.** Assume the continuum hypothesis. Let $f$ be a pure state on $\mathcal{B}(H)$ and let $\mathcal{A} \subseteq \mathcal{B}(H)$ be a separable unital $C^*$-algebra. Then there is a separable unital $C^*$-algebra $\mathcal{B}$ that contains $\mathcal{A}$ such that the restriction of $f$ to $\mathcal{B}$ is pure.

**Proof.** The cardinality of $\mathcal{B}(H)$ is $2^{\aleph_0}$. By the continuum hypothesis we can enumerate the elements of $\mathcal{B}(H)$ as $\{x_\alpha : \alpha < \aleph_1\}$. For each $\alpha < \aleph_1$ let $\mathcal{A}_\alpha$ be the unital $C^*$-algebra generated by $\mathcal{A}$ and $\{x_\beta : \beta < \alpha\}$.

Let $x = x_\gamma \in \mathcal{B}(H)$. We claim that for sufficiently large $\alpha > \gamma$ we have, for any states $f_1$ and $f_2$ on $\mathcal{A}_\alpha$,

$$f|_{\mathcal{A}_\alpha} = (f_1 + f_2)/2 \quad \text{implies} \quad f_1(x) = f_2(x).$$

(If this condition holds we say that $f|_{\mathcal{A}_\alpha}$ is pure on $x$.) To see this, suppose the claim fails. Then there exist $\epsilon > 0$, an unbounded set $T \subseteq \aleph_1$, and for each $\alpha \in T$ states $f_1^\alpha$ and $f_2^\alpha$ on $\mathcal{A}_\alpha$ such that

$$f|_{\mathcal{A}_\alpha} = (f_1^\alpha + f_2^\alpha)/2 \quad \text{and} \quad |f_1^\alpha(x) - f_2^\alpha(x)| \geq \epsilon. \quad (*)$$

(If no such $\epsilon$ and $T$ existed, then for each $n \in \mathbb{N}$ we could find $\beta_n < \aleph_1$ such that $(\ast)$ cannot be achieved with $\epsilon = 1/n$ for any $\alpha \geq \beta_n$. This would imply that $f|_{\mathcal{A}_\alpha}$ is pure on $x$ for all $\alpha > \sup \beta_n$, contradicting our assumption that the claim fails.)

Let $\mathcal{U}$ be an ultrafilter over $T$ that contains the set $\{\alpha \in T : \alpha > \beta\}$ for each $\beta < \aleph_1$, and define states $f_1$ and $f_2$ on $\mathcal{B}(H)$ by $f_1(y) = \lim_{\mathcal{U}} f_1^\alpha(y)$ and $f_2(y) = \lim_{\mathcal{U}} f_2^\alpha(y)$ for all $y \in \mathcal{B}(H)$. Then $f = (f_1 + f_2)/2$ and $|f_1(x) - f(x)| \geq \epsilon$, so that $f \neq f_1$. This contradicts the assumption that $f$ is pure, so the claim is established.

Now for any $\alpha < \aleph_1$, we can find a countable dense subset of $\mathcal{A}_\alpha$, and the claim implies that for sufficiently large $\beta$, $f|_{\mathcal{A}_\beta}$ is pure on every element of this subset. Since the subset is dense, $f|_{\mathcal{A}_\beta}$ is pure on every $x \in \mathcal{A}_\alpha$.

Now construct a sequence $(\alpha_n)$ by setting $\alpha_0 = 0$ and choosing $\alpha_{n+1} > \alpha_n$ such that $f|_{\mathcal{A}_{\alpha_{n+1}}}$ is pure on every $x \in \mathcal{A}_{\alpha_n}$. Letting $\beta = \sup \alpha_n$, we then have that $f|_{\mathcal{A}_\beta}$ is pure on every element of $\bigcup_{\alpha < \beta} \mathcal{A}_\alpha$; since this is a dense subset of $\mathcal{A}_\beta$, $f|_{\mathcal{A}_\beta}$ is a pure state on $\mathcal{A}_\beta$. Thus $\mathcal{B} = \mathcal{A}_\beta$ is a separable unital $C^*$-algebra that contains $\mathcal{A}$ such that the restriction of $f$ to $\mathcal{B}$ is pure. \hfill \qed

**Theorem 13.5.** Assume the continuum hypothesis. Then there is a pure state on $\mathcal{B}(H)$ that is not diagonalizable.

**Proof.** There are $2^{\aleph_0}$ elements of $\mathcal{B}(H)$ and $2^{\aleph_0}$ orthonormal bases of $H$. Enumerate these as $\{x_\alpha : \alpha < \aleph_1\}$ and $\{(e_\alpha) : \alpha < \aleph_1\}$. We recursively construct a nested transfinite sequence of separable unital $C^*$-algebras $\mathcal{A}_\alpha$ together with pure states $f_\alpha$ on $\mathcal{A}_\alpha$ such that for all $\alpha < \aleph_1$ we have

(i) $x_\alpha \in \mathcal{A}_{\alpha+1}$;
(ii) if $\beta < \alpha$ then $f_\alpha|_{\mathcal{A}_\beta} = f_\beta$; and
(iii) $\mathcal{A}_{\alpha+1}$ contains an orthogonal projection $P_\alpha$ diagonalized by $(e_\alpha)$ such that $0 < f_\alpha + 1(P_\alpha) < 1$.

Begin by letting $\mathcal{A}_0$ be the closure of $\{A + zI : A$ is finite rank and $z \in \mathbb{C}\}$ and defining $f_0(A + zI) = z$. At successor stages, use Lemma 13.3 to find an orthogonal projection $P_\alpha$ that is diagonalized by $(e_\alpha)$ and a pure state $g$ on $\mathcal{B}(H)$ such that $g|_{\mathcal{A}_\alpha} = f_\alpha$ and $0 < g(P_\alpha) < 1$. Then use Lemma 13.4 to find a separable unital $C^*$-algebra $\mathcal{A}_{\alpha+1}$ which contains $\mathcal{A}_\alpha$, $x_\alpha$, and $P_\alpha$ and such that the restriction $f_{\alpha+1}$ of $g$ to $\mathcal{A}_{\alpha+1}$ is pure. At limit ordinals $\alpha$, let $\mathcal{A}_\alpha$ be the closure of $\bigcup_{\beta < \alpha} \mathcal{A}_\beta$. In this case the state $f_\alpha$ is determined by continuity and the condition that $f_\alpha|_{\mathcal{A}_\beta} = f_\beta$; it is pure because if $g_1$ and $g_2$ are states on $\mathcal{A}_\alpha$ such that $f_\alpha = (g_1 + g_2)/2$, then for all $\beta < \alpha$ purity of $f_\beta$ implies that $g_1$ and $g_2$ have the same restriction to $\mathcal{A}_\beta$, so that $g_1 = g_2$. This completes the description of the recursive construction.

Finally, define a state $f$ on $\mathcal{B}(H)$ by letting $f|_{\mathcal{A}_\alpha} = f_\alpha$. By the reasoning used immediately above, $f$ is pure, and since $0 < f(P_\alpha) < 1$ for all $\alpha$, it is not diagonalized by any orthonormal basis $(e_\alpha)$. \hfill \qed
Exercises

(a) Prove that the set of states on a unital C*-algebra is convex and weak*-compact.
(b) Let \((a_n)\) and \((b_n)\) be bounded sequences of complex numbers and let \(U\) be an ultrafilter over \(\mathbb{N}\). Prove that \(\lim_U(a_n + b_n) = \lim_U a_n + \lim_U b_n\).
(c) Show that the state \(f_0\) defined on \(A_0\) in the proof of Theorem 13.5 is pure. (Hint: if \(P\) is an orthogonal projection such that \(I - P\) has finite rank, then \(f_0(P) = 1\). Every finite rank operator is a linear combination of rank one orthogonal projections.)

C. Akemann and N. Weaver, \(\mathcal{B}(H)\) has a pure state that is not multiplicative on any MASA, *Proc. Nat. Acad. Sci. USA*, to appear.

14. The diamond principle

Consider an infinite binary tree. If one vertex is removed from each level except the first, there will still be an infinite path down the tree. Such a path can be recursively constructed starting at the top vertex, since each vertex in the original tree has two immediate successors, so that after vertices are removed at least one immediate successor will always still be available. Thus the construction can proceed indefinitely.

Avoiding forbidden vertices

Now consider the analogous question for the standard \(\mathfrak{N}_1-\mathfrak{N}_1\)-tree. This tree has \(\mathfrak{N}_1\) levels and each vertex has \(\mathfrak{N}_1\) immediate successors. The vertices at level \(\alpha\) can be labelled by functions from \(\alpha\) into \(\mathfrak{N}_1\); if \(\alpha < \beta\) then a vertex \(w\) at level \(\beta\) lies below a vertex \(v\) at level \(\alpha\) if the function that labels \(w\) extends the function that labels \(v\). Remove one vertex from each level except the first. Will there necessarily still be at least one path all the way down the tree?

The binary tree argument does not work here. The problem is that when we try to recursively construct a path down the tree, the vertex we hit at a limit ordinal is determined by the sequence of vertices chosen up to that point. (If \(\alpha\) is a limit ordinal then any function from \(\alpha\) to \(\mathfrak{N}_1\) is determined by its restrictions to all ordinals strictly less than \(\alpha\).) Thus, when attempting to construct a path down the tree, in order to avoid forbidden vertices at limit levels we would have to look ahead somehow. It is not clear that this can be done.

**Definition 14.1.** A subset \(C\) of \(\mathfrak{N}_1\) is **closed** if the supremum of every countable subset of \(C\) lies in \(C\), and it is **unbounded** if for every \(\alpha < \mathfrak{N}_1\) there exists \(\beta \in C\) such that \(\beta > \alpha\). (Thus, \(C\) is unbounded if and only if it is uncountable.) A subset of \(\mathfrak{N}_1\) is **stationary** if it intersects every closed unbounded subset. The **diamond principle** (\(\Diamond\)) asserts that one vertex can be chosen from each level of the standard \(\mathfrak{N}_1-\mathfrak{N}_1\)-tree in such a way that every path down the tree meets the chosen vertices on a stationary set of levels.

Less formally: one vertex can be chosen from each level so that every path down the tree repeatedly meets chosen vertices. More formally: there is a sequence \(\{h_\alpha : \alpha < \mathfrak{N}_1\}\) of functions \(h_\alpha : \alpha \to \mathfrak{N}_1\) such that for any function \(f : \mathfrak{N}_1 \to \mathfrak{N}_1\) the set

\[\{\alpha : f|_\alpha = h_\alpha\}\]
is a stationary subset of $\aleph_1$.

The diamond principle implies the continuum hypothesis (exercise), so $\neg \Diamond$ follows from $\neg \text{CH}$ and hence is relatively consistent with ZFC. We will now show that $\Diamond$ is also relatively consistent with ZFC. In $M$, define a notion of forcing $P$ as follows. The elements of $P$ are all sequences $p = \{ h_\gamma : \gamma < \alpha \}$ such that $\alpha$ is a countable ordinal and $h_\gamma$ is a function from $\gamma$ into $\aleph_1$, for each $\gamma$. (Thus, $p$ chooses one vertex from each level of the tree up to level $\alpha$.) We call $\alpha$ the length of $p$. Order the elements of $P$ by letting $p \leq q$ if the sequence $p$ extends the sequence $q$.

**Theorem 14.2.** Let $P$ be the notion of forcing defined above. Then $\Diamond$ is true in $M[G]$, for any generic filter $G$.

**Proof.** It is clear that $M \models \text{“} P \text{ is } \omega\text{-closed} \text{”}$, so $\aleph_1^M = \aleph_1^{M[G]}$. As usual, the union of $G$ is a sequence $\{ h_\alpha : \alpha < \aleph_1 \}$ such that each $h_\alpha$ is a function from $\alpha$ into $\aleph_1$. We must show that in $M[G]$ the restrictions of any function $f : \aleph_1^M \rightarrow \aleph_1^M$ agree with the $h_\alpha$ on a stationary set.

Let $f$ be a function in $M[G]$ from $\aleph_1^M$ to itself and let $C \subseteq \aleph_1^M$ be a subset in $M[G]$ such that $M[G] \models \text{“} C \text{ is closed and unbounded} \text{”}$. Let $\tau$ be a $P$-name for $f$ and let $\sigma$ be a $P$-name for $C$, and find $p \in G$ such that $p \models \text{“} \tau \text{ is a function from } \aleph_1 \text{ to itself and } \sigma \text{ is a closed and unbounded subset of } \aleph_1 \text{”}$. Working in $M$, for any $r \leq p$ we now recursively define a sequence $p_0 \geq p_1 \geq \cdots$. Let $p_0 = r$. Having chosen $p_n$, we choose $p_{n+1}$ as follows. Say the length of $p_n$ is $\alpha_n$. Since $p \models \text{“} \sigma \text{ is unbounded} \text{”,}$ for any generic filter $G'$ that contains $p_n$ we have that $M[G'] \models \text{“} \text{there exists } \beta > \alpha_n \text{ in } \text{val}_G(\sigma) \text{”}$. Hence there exists $q_n < p_n$ which forces $\beta_n \in \sigma$, for some $\beta_n > \alpha_n$. We may assume that the length of $q_n$ is at least $\beta_n$. Similarly, we can find $p_{n+1} \leq q_n$ such that $p_{n+1}$ forces $\text{“} \tau|_{\alpha_n} = f(q_n) \text{”}$ for some function $f_n : \alpha_n \rightarrow \aleph_1^M$ in $M$. (Here we use the fact that $P$ is $\omega$-closed: by Lemma 9.2 and the fact that $\alpha_n$ is countable in $M$, the evaluation of $\tau$ restricted to $\alpha_n$ belongs to $M$, for any generic filter that contains $q_n$.)

We have constructed $(p_n)$ in $M$. Let $q$ be the union of the sequences $p_n$, so that the length of $q$ is $\alpha^* = \sup \alpha_n$. Also, since $\alpha_n < \beta_n \leq \alpha_{n+1}$ we have $\alpha^* = \sup \beta_n$. Since $q \leq q_n$ for all $n$, we have $q \models \text{“} \beta_n \in \sigma \text{”.}$ Since $q \models \text{“} \sigma \text{ is closed} \text{”}$ we must have $q \models \text{“} \bar{\alpha^*} \in \sigma \text{”.}$ Finally, let $q' = \{ q_\gamma : \gamma < \alpha^* + 1 \}$ be the sequence of length $\alpha^* + 1$ which extends $q$ by the one additional function $g_{\alpha^*} : \alpha^* \rightarrow \aleph_1$ defined by taking the union of the functions $f_n$. Since $q' \leq p_{n+1}$, it forces $\text{“} \text{the restriction of } \tau \text{ to } \alpha_n \text{ equals the restriction of } g_{\alpha^*} \text{ to } \alpha_n \text{”}$ for all $n$; thus, $q'$ forces $\text{“} \text{the restriction of } \tau \text{ to } \bar{\alpha^*} \text{ equals } g_{\alpha^*} \text{”}$.

We conclude that $q'$ forces $\text{“} \bar{\alpha^*} \in \sigma \text{ and } \tau \text{ restricted to } \bar{\alpha^*} \text{ is in the union of } \Gamma \text{”}$, Thus, we have shown that any $r \leq p$ lies above some $q'$ which forces that $\tau$ restricted to some element of $\sigma$ equals a function in the union of $\Gamma$. So the set of such $q'$ is dense below $p$, and since $G$ is generic it must contain such a point. This means that $M[G] \models \text{“} (\exists \alpha)(\alpha \in C \text{ and } f|_\alpha = h_\alpha) \text{”}$. Thus, in $M[G]$ the set of $\alpha$ for which the restriction of any given function from $\aleph_1$ to $\alpha$ equals $h_\alpha$ is stationary. $\blacksquare$

**Exercises**

(a) Prove that the intersection of countably many closed unbounded subsets of $\aleph_1$ is a closed unbounded subset of $\aleph_1$.

(b) Prove that $\Diamond$ implies CH.

**15. Application: Suslin’s problem.**

We work in ZFC. The real line is dense (between any two points there is a third), unbounded (there is no least or greatest element), complete (every bounded set has a least upper bound and a greatest lower bound), and separable. Conversely, it is not too hard to show that any totally ordered set with these properties is order-isomorphic to $\mathbb{R}$. Suslin’s problem asks whether “separable” can be weakened to “there is no uncountable collection of disjoint open intervals” in this characterization. This condition is called c.c.c.

**Definition 15.1.** A Suslin line is a totally ordered set that is dense, unbounded, complete, and c.c.c. but not order-isomorphic to $\mathbb{R}$. 

27
The existence of Suslin lines is independent of ZFC. In this section we will show that diamond implies that Suslin lines exist.

The key technical step is a reduction to a problem about trees.

**Definition 15.2.** A tree is a partially ordered set with the property that for any \( x \) in \( T \) the set \( \{ y \in T : y > x \} \) is reverse well-ordered.

(a) If \( T \) is a tree and \( x \in T \), the height of \( x \) is the ordinal reverse isomorphic to \( \{ y : y > x \} \). A level of \( T \) is the set of all vertices of a given height. The height of \( T \) is the supremum of the heights of its vertices.

(b) A branch in \( T \) is a maximal totally ordered subset, and an antichain is a set of pairwise incomparable elements.

(c) \( T \) is a Suslin tree if its height is \( \aleph_1 \), every branch is countable, and every antichain is countable. It is normal if additionally

(i) it has a unique greatest element;

(ii) every vertex has infinitely many immediate successors;

(iii) every vertex has descendants at every level \( \alpha < \aleph_1 \); and

(iv) at any limit level, no two distinct vertices have exactly the same predecessors.

**Lemma 15.3.** Suslin lines exist if and only if normal Suslin trees exist.

**Proof.** (⇒) Given a Suslin line, we create a Suslin tree as follows. Let \( I_0 \) be an arbitrary nondegenerate closed interval in the line. For \( \alpha < \aleph_1 \) we recursively choose \( I_\alpha \) to be a nondegenerate closed interval that does not contain either endpoint of any interval \( I_\beta \) with \( \beta < \alpha \). We can do this because the set of all endpoints to be avoided is countable and hence not dense in the line, since a Suslin line cannot be separable. The vertices of the tree are the countable ordinals, ordered by setting \( \alpha \preceq \beta \) if \( I_\alpha \subseteq I_\beta \).

We verify that the resulting tree is Suslin. The nonexistence of uncountable antichains follows from the fact that one cannot find uncountably many disjoint intervals \( I_\alpha \) (since the original line was Suslin). Similarly, any branch corresponds to a nested sequence of intervals; the left endpoints of these intervals are then an increasing sequence in the line, so that they constitute the endpoints of a family of disjoint intervals. Again, since the original line was c.c.c., any such sequence must be countable. So the tree has no uncountable branches.

Finally, it is an exercise to show that every Suslin tree can be converted into a normal Suslin tree.

(⇐) Given a normal Suslin tree, first assign an order to the immediate successors of each vertex, making them order-isomorphic to the rationals. Then define a Suslin line by letting its points be the branches of the tree, ordered lexicographically according to the orderings just introduced. It is clear that the resulting totally ordered set is dense and has no least or greatest element. It is c.c.c. because for any open interval we can find a vertex \( x \) such that all branches passing through \( x \) lie in the interval, so an uncountable family of disjoint open intervals would give rise to an uncountable antichain in the original tree. It is not separable because any countable set of branches have heights less than some countable ordinal, and any point at any lower level is contained in an interval of branches that evidently does not meet the original set of branches. Finally, we obtain a Suslin line by completing.

**Lemma 15.4.** Let \( T \) be a tree of height \( \aleph_1 \) and let \( A \) be a maximal antichain in \( T \). For each \( \alpha < \aleph_1 \) let \( T_\alpha \) be the set of vertices of height less than \( \alpha \) and suppose each \( T_\alpha \) is countable. Then

\[
C = \{ \alpha : A \cap T_\alpha \text{ is a maximal antichain in } T_\alpha \}
\]

is a closed unbounded subset of \( \aleph_1 \).

**Proof.** For any \( \alpha, A \cap T_\alpha \) is an antichain in \( T_\alpha \). If \( \alpha = \sup \alpha_\alpha \) and \( A \cap T_\alpha \) is a maximal antichain in each \( T_\alpha \), then any element of \( T_\alpha \) belongs to some \( T_\alpha \) and hence is comparable to some element of \( A \cap T_\alpha \); thus \( \alpha \in C \). So \( C \) is closed.
To see that $C$ is unbounded, let $\alpha < \aleph_1$. Then $T_\alpha$ is countable and every element of $T_\alpha$ is comparable to some element of $A$, so there exists $\alpha_1 \geq \alpha$ such that every element of $T_\alpha$ is comparable to some element of $A \cap T_{\alpha_1}$. Then find $\alpha_2 \geq \alpha_1$ such that every element of $T_{\alpha_1}$ is comparable to some element of $A \cap T_{\alpha_2}$, and so on. Setting $\alpha^* = \sup \alpha_\alpha$, we have that every element of $T_{\alpha^*}$ is comparable to some element of $A \cap T_{\alpha^*}$, i.e., $\alpha^* \in C$. Since $\alpha^* \geq \alpha$ and $\alpha$ was arbitrary, this shows that $C$ is unbounded.

**Theorem 15.5.** Assume $\Diamond$. Then Suslin lines exist.

**Proof.** Using $\Diamond$, fix a sequence $\{h_\alpha : \alpha < \aleph_1\}$ of functions $h_\alpha : \alpha \to \{0,1\}$ such that for any function $f : \aleph_1 \to \{0,1\}$ the set $\{\alpha : f|_\alpha = h_\alpha\}$ is a stationary subset of $\aleph_1$. We construct a normal Suslin tree $T$ whose vertices are all countable ordinals. We take the ordinals in order, i.e., every time we add a vertex it will be the first ordinal not used up to that point.

Let 0 be the top vertex. Having constructed all vertices at level $\alpha$, we add a countably infinite number of immediate successors to each vertex at level $\alpha$ to obtain the vertices at level $\alpha+1$. We construct the vertices at a limit level $\alpha$ as follows. Let $\beta$ be the least ordinal not yet used as a vertex and let $S_\beta = \{\gamma < \beta : h_\beta(\gamma) = 0\}$. Using the notation of Lemma 15.4, if $S_\beta$ is not a maximal antichain in $T_\alpha$, then for each $\gamma < \beta$ choose a path of height $\alpha$ containing $\gamma$ (it will be clear inductively that this can always be done) and add a vertex at level $\alpha$ below this path. If $S_\beta$ is a maximal antichain in $T_\alpha$, then do the same thing but ensure that the path of height $\alpha$ containing $\gamma$ also contains a point of $S_\beta$. We can do this because $S_\beta$ is maximal. This completes the description of the construction.

We must show that every branch is countable and every antichain is countable; the other properties of a normal Suslin tree are clear from the construction. Let $A$ be a maximal antichain; by Lemma 15.4 the set of $\alpha$ such that $A \cap T_\alpha$ is maximal in $T_\alpha$ is closed and unbounded. Also, the set of $\alpha$ such that $T_\alpha = \alpha$ is easily seen to be closed and unbounded, so by $\Diamond$ there exists $\alpha$ such that $T_\alpha = \alpha$ and $S_\alpha = A \cap T_\alpha$ is a maximal antichain in $T_\alpha$. By the construction, every vertex at level $\alpha$ then lies below some element of $S_\alpha$, and this must remain true at all future levels. Thus $A = A \cap T_\alpha$, and hence it is countable. We have shown that every antichain in $T$ is countable.

Finally, there is no uncountable branch because this would easily imply the existence of uncountable antichains. (For each vertex in the branch, choose an immediate successor that does not lie in the branch. The set of these successors is an antichain.)

**Exercises**

(a) Show that if a Suslin tree exists then a normal Suslin tree exists. (Hint: Given a Suslin tree, first remove any vertex that has descendants at only countably many levels. Then remove any vertex that has only one immediate successor, but do not necessarily remove the descendants of such vertices. Then insert vertices to accomodate condition (iv). Next remove all vertices at all successor levels, and finally handle condition (i).)

**16. Application: Naimark’s problem**

We work in ZFC. Recall that C*-algebras are defined concretely as closed linear subspaces of $\mathcal{B}(H)$ that are stable under products and adjoints. We now allow $H$ to be nonseparable. Isomorphic C*-algebras can be realized as acting on different Hilbert spaces in different ways; a representation of a C*-algebra $\mathcal{A}$ on a Hilbert space $K$ is a bounded linear map $\pi : \mathcal{A} \to \mathcal{B}(K)$ which preserves products and adjoints. It is irreducible if $K$ cannot be nontrivially decomposed into an orthogonal direct sum $K = K_1 \oplus K_2$ in such a way that each summand is invariant for the action of $\mathcal{A}$ (that is, $\pi(x)K_i \subseteq K_i$ for all $x \in \mathcal{A}$ and $i = 1,2$). If $\pi' : \mathcal{A} \to \mathcal{B}(K')$ is another representation of $\mathcal{A}$, we say that $\pi$ and $\pi'$ are unitarily equivalent if there is a unitary operator $U : K \to K'$ such that $\pi(x) = U^{-1}\pi'(x)U$ for all $x \in \mathcal{A}$.

Irreducible representations are related to pure states by the following facts from basic C*-algebra theory. If $\pi$ is an irreducible representation of $\mathcal{A}$ on $\mathcal{B}(K)$ and $v$ is a unit vector in $K$, then $x \mapsto \langle \pi(x)v, v \rangle$ is a pure state on $\mathcal{A}$. Every pure state is realized in this way for some irreducible representation. If $\mathcal{A}$ is unital
then two irreducible representations are unitarily equivalent if and only if (some or any) corresponding pure states are unitarily equivalent in the following sense.

**Definition 16.1.** Two pure states \( \rho_1 \) and \( \rho_2 \) on a unital C*-algebra \( A \) are **unitarily equivalent** if there is a unitary \( u \in A \) such that \( \rho_1(x) = \rho_2(u^* xu) \) for all \( x \in A \).

For any Hilbert space \( H \), the C*-algebra of compact operators on \( H, K(H) \), is the closure of the set of finite rank operators. Mark Naimark proved that \( K(H) \) has only one irreducible representation up to unitary equivalence, namely the identity representation on \( H \), and he asked whether any other C*-algebra has only one irreducible representation. Alex Rosenberg quickly showed that there were no separable examples. Recently Charles Akemann and I used diamond to construct a nonseparable example. We now give this result, modulo various basic C*-algebraic facts and omitting the proof of one key C*-algebraic lemma.

Whether it is relatively consistent with ZFC that no examples exist remains open.

A C*-algebra is **simple** if it contains no nontrivial closed two-sided ideals. If \( A_1 \subseteq A_2 \subseteq \cdots \) is a nested sequence of simple C*-algebras and \( A \) is the completion of the union \( \bigcup A_n \), it is standard that \( A \) is also simple. We omit the proof of the following lemma.

**Lemma 16.2.** Let \( A \) be a simple, separable, unital C*-algebra and let \( f \) and \( g \) be unitarily inequivalent pure states on \( A \). Then there is a simple, separable, unital C*-algebra \( B \) that unitally contains \( A \) such that \( f \) and \( g \) have unique extensions to pure states on \( A \), and these extensions are unitarily equivalent.

(\( B \) **unitally contains** \( A \) if the unit of \( B \) equals the unit of \( A \).)

**Lemma 16.3.** Let \( (A_\alpha) \), \( \alpha < \aleph_1 \), be a nested transfinite sequence of separable C*-algebras and suppose \( A_\alpha \) is the completion of \( \bigcup_{\beta<\alpha} A_\beta \), for every limit ordinal \( \alpha \). Then \( A = \bigcup_{\alpha<\aleph_1} A_\alpha \) is a C*-algebra, and if \( f \) is a pure state on \( A \) then \( \{ \alpha < \aleph_1 : f \text{ restricts to a pure state on } A_\alpha \} \) is closed and unbounded.

**Proof.** \( A \) is complete because any Cauchy sequence in \( A \) must lie in \( A_\alpha \) for some \( \alpha \), and hence must have a limit in \( A_\alpha \subseteq A \). Using an abstract characterization of C*-algebras, it easily follows that \( A \) is a C*-algebra.

Let \( f \) be a pure state on \( A \), let \( (\alpha_n) \) be a sequence of countable ordinals such that \( f|A_{\alpha_n} \) is pure for all \( n \), and let \( \alpha = \sup \alpha_n \). Then \( f|A_\alpha \) must be pure because if \( f|A_\alpha = (f_1 + f_2)/2 \) for some states \( f_1 \) and \( f_2 \) on \( A_\alpha \), then for all \( n \) the restrictions of \( f_1 \) and \( f_2 \) to \( A_{\alpha_n} \) must agree by purity of \( f|A_{\alpha_n} \). Thus \( f_1 = f_2 \), using the fact that \( A_\alpha \) is the completion of \( \bigcup A_{\alpha_n} \). This shows that the set of \( \alpha \) such that \( f|A_\alpha \) is pure is closed. The proof that it is unbounded is essentially the same as the proof of Lemma 13.4.

**Theorem 16.4.** Assume \( \diamond \). Then there is a C*-algebra generated by \( \aleph_1 \) elements that has only one irreducible representation up to unitary equivalence but is not isomorphic to the algebra of compact operators on any Hilbert space.

**Proof.** By diamond, choose a sequence \( \{ h_\alpha : \alpha < \aleph_1 \} \) of functions \( h_\alpha : \alpha \to \aleph_1 \) such that for any function \( f : \aleph_1 \to \aleph_1 \) the set \( \{ \alpha : f|A_\alpha = h_\alpha \} \) is a stationary subset of \( \aleph_1 \). For \( \alpha < \aleph_1 \) we recursively construct a nested transfinite sequence of simple separable unital C*-algebras \( A_\alpha \), all with the same unit, together with a pure state \( f_\alpha \) on \( A_\alpha \) and an injective function \( \phi_\alpha \) from the set of states on \( A_\alpha \) into \( \aleph_1 \). We will ensure that for any \( \alpha < \beta \) the state \( f_\alpha \) has a unique extension to a state on \( A_\beta \) and \( f_\beta \) is this extension.

Begin by letting \( A_0 \) be any simple, separable, infinite dimensional, unital C*-algebra. (There are many examples of these. For instance, unitally embed \( M_{2^n}(C) = B(C^{2^n}) \) in \( M_{2^{n+1}}(C) \) by the map \( A \mapsto \begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix} \) and take the completion of the union. The result will be simple by a fact mentioned earlier which states that the completion of a union of a nested sequence of simple C*-algebras is always simple.) Let \( f_0 \) be any pure state on \( A_0 \) (a basic fact from convexity theory: every C*-algebra has pure states). Since \( \diamond \) implies CH (§ 14, Exercise (b)), the set of states on \( A_0 \) has cardinality at most \( \aleph_1 \), so let \( \phi_0 \) be any injective function from the set of states on \( A_0 \) into \( \aleph_1 \).
Having constructed \( A_\alpha \), we define \( A_{\alpha+1} \) as follows. If \( \alpha \) is a limit ordinal and there is a pure state \( g_\alpha \) on \( A_\alpha \) that is not unitarily equivalent to \( f_\alpha \) and such that \( h_\alpha(\beta) = \phi_\beta(g_\alpha|_{A_\beta}) \) for all \( \beta < \alpha \), then let \( A_{\alpha+1} \) be the C*-algebra given by Lemma 16.2 with \( f = f_\alpha \) and \( g = g_\alpha \). Also let \( f_{\alpha+1} \) be the unique extension of \( f_\alpha \) to \( A_{\alpha+1} \) and let \( \phi_{\alpha+1} \) be any injective function from the set of states on \( A_{\alpha+1} \) into \( \mathbb{N}_1 \). Otherwise, let \( A_{\alpha+1} = A_\alpha \), \( f_{\alpha+1} = f_\alpha \), and \( \phi_{\alpha+1} = \phi_\alpha \).

At limit stages \( \alpha \), we let \( A_\alpha \) be the completion of \( \bigcup_{\beta < \alpha} A_\beta \), define \( f_\alpha \) by the condition that its restriction to \( A_\beta \) is \( f_\beta \) for all \( \beta < \alpha \), and let \( \phi_\alpha \) be any injective function from the set of states on \( A_\alpha \) into \( \mathbb{N}_1 \). Again, note that \( A_\alpha \) is simple because it is the completion of the union of a nested sequence of simple C*-algebras. This completes the description of the construction of the sequence \( (A_\alpha) \).

Let \( A = \bigcup_{\alpha < \mathbb{N}_1} A_\alpha \) and define a state \( f \) on \( A \) by requiring \( f|_{A_\alpha} = f_\alpha \) for all \( \alpha \). Then \( A \) is a C*-algebra by Lemma 16.3, and \( f \) is pure by the argument used in the proof of Lemma 16.3 to verify closure. We must show that every pure state on \( A \) is unitarily equivalent to \( f \). Let \( g \) be any pure state on \( A \); we will show that \( g|_{A_\alpha} \) is unitarily equivalent to \( f_\alpha \) for some \( \alpha \). This is sufficient because \( f_\alpha \) has a unique state extension to \( A \) (namely \( f \)), so conjugation by the unitary that makes \( g|_{A_\alpha} \) and \( f_\alpha \) equivalent shows that \( g|_{A_\alpha} \) has a unique state extension to \( A \) (namely, \( g \)), which is unitarily equivalent to \( f \).

Define \( h : \mathbb{N}_1 \to \mathbb{N}_1 \) by setting \( h(\alpha) = \phi_\alpha(g|_{A_\alpha}) \). Let \( S \) be the set of limit ordinals such that \( g|_{A_\alpha} \) is pure. By Lemma 16.3 together with the fact that the set of limit ordinals less than \( \mathbb{N}_1 \) is closed and unbounded, it follows that \( S \) is closed and unbounded. Thus by \( \diamond \) there exists a limit ordinal \( \alpha \) such that \( g|_{A_\alpha} \) is pure and \( h_\alpha = h|_{\alpha} \), i.e.,

\[ h_\alpha(\beta) = \phi_\beta(g|_{A_\beta}) \]

for all \( \beta < \alpha \). If \( g_\alpha \) is unitarily equivalent to \( f_\alpha \), then we are done; otherwise the construction of \( f_{\alpha+1} \) guarantees that it is unitarily equivalent to the unique extension of \( g|_{A_\alpha} \) to \( A_{\alpha+1} \), which must be \( g|_{A_{\alpha+1}} \).

Thus we are done in this case as well.

Finally, \( A \) is not isomorphic to any \( \mathcal{K}(H) \) because it is both infinite dimensional and unital.

### References

### 17. Product forcing and \( \diamond^S \)

Working in ZFC*, we have developed a procedure for enlarging the given model \( M \) of ZFC to another model \( M[G] \) using a preordered set in \( M \). But now the same procedure can be applied to \( M[G] \); that is, we can enlarge \( M[G] \) to another model of ZFC in exactly the same way, using a preordered set in \( M[G] \). As we will see in § 19 and subsequent sections, iterating this process increases the power of the forcing technique. In this section we will adopt the opposite point of view and see how in some circumstances the passage from \( M \) to \( M[G] \) can be broken up into two stages. This can be useful in determining the properties of \( M[G] \).

**Definition 17.1.** Let \( P_1 \) and \( P_2 \) be two notions of forcing. The **product notion of forcing** \( P_1 \times P_2 \) is the cartesian product of \( P_1 \) and \( P_2 \) equipped with the preorder defined by \( (p, q) \leq (p', q') \) if \( p \leq p' \) and \( q \leq q' \).

**Theorem 17.2.** Let \( P_1 \) and \( P_2 \) be two notions of forcing.

(a) If \( G_1 \) is a generic filter of \( P_1 \) relative to \( M \) and \( G_2 \) is a generic filter of \( P_2 \) relative to \( M[G_1] \), then \( G = G_1 \times G_2 \) is a generic filter of \( P_1 \times P_2 \) relative to \( M \).
We claim that $D$ for any stationary set $S$ in $\mathcal{M}$, we must show that $G$ intersects $D$.

Define

$$D' = \{ q \in P_2 : (p, q) \in D \text{ for some } p \in G_1 \}.$$ 

We claim that $D'$ is dense in $P_2$. To see this, let $r \in P_2$ and let

$$D'' = \{ p \in P_1 : (p, q) \in D \text{ for some } q \leq r \}.$$ 

Since $D$ is dense in $P_1 \times P_2$, for any $p \in P_1$ the point $(p, r)$ lies above an element of $D$, and this shows that $D''$ is dense in $P_1$. Thus $G_1$ intersects $D''$; fix $p \in G_1 \cap D''$ and fix $q \leq r$ such that $(p, q) \in D$. Then $q \in D'$, and this verifies the claim.

Since $D'$ is dense in $P_2$ and $D' \in \mathcal{M}[G_1]$, $G_2$ must intersect $D'$. Fix $q' \in G_2 \cap D'$ and fix $p' \in G_1$ such that $(p', q') \in D$. Then $(p', q') \in G \cap D$. Thus $G$ is generic.

(b) Let $G_1 = \{ p \in P_1 : (p, 1_{P_1}) \in G \}$ and $G_2 = \{ q \in P_2 : (1_{P_1}, q) \in G \}$. For any $(p, q) \in G$ we have $(p, 1_{P_1}), (1_{P_1}, q) \in G$; this shows that $G \subseteq G_1 \times G_2$. Conversely, if $p \in G_1$ and $q \in G_2$ then $(p, 1_{P_1}), (1_{P_1}, q) \in G$ and by the filter property $G$ must contain a common extension of $(p, 1_{P_1})$ and $(1_{P_1}, q)$. But $(p, q)$ is their greatest lower bound in $P_1 \times P_2$, so $G$ must contain $(p, q)$. Thus $G_1 \times G_2 \subseteq G$. We conclude that $G = G_1 \times G_2$.

We will show that $G_2$ is a generic filter of $P_2$ relative to $\mathcal{M}[G_1]$. A similar argument shows that $G_1$ is a generic filter of $P_1$ relative to $\mathcal{M}[G_2]$, which trivially implies that it is generic relative to $\mathcal{M}$.

Thus, let $D \in \mathcal{M}[G_1]$ be a dense subset of $P_2$. Let $\tau \in \mathcal{M}$ be a $P_1$-name for $D$ and fix $p_0 \in G_1$ such that $p_0 \models \tau$. Define

$$D' = \{ (p, q) \in P_1 \times P_2 : p \leq p_0 \text{ and } p \models \neg \bar{q} \in \tau \}.$$ 

We claim that $D'$ is dense below $(p_0, 1_{P_2})$. To see this let $(r, s) \leq (p_0, 1_{P_2})$. Then $r \models \neg \exists x \in \tau$ such that $x \leq \bar{s}$ since $r \leq p_0$. Thus some $r' \leq r$ forces $\exists s' \in \tau$ and $s' \leq \bar{s}$ for some $s$, so that $(r', s') \in D'$ and $(r', s') \leq (r, s)$. This proves the claim.

Since $G$ is generic and $(p_0, 1_{P_2}) \in G$, there must exist $(p, q) \in G \cap D'$. Then $q \in G_2$, and $p \models \neg \bar{q} \in \tau$ implies that $q \in D$. This shows that $G_2$ is generic relative to $\mathcal{M}[G_1]$.

For the final statement of the theorem, observe that $G_1$, $G_2$, and $G$ all belong to both $\mathcal{M}[G]$ and $\mathcal{M}[G_1][G_2]$.

The fact that $\mathcal{M}[G] \subseteq \mathcal{M}[G_1][G_2]$ is then a straightforward induction on name rank, as is the reverse containment.

We will now illustrate the way product decompositions can be employed by using them to prove a slightly stronger version of the diamond principle.

**Definition 17.3.** For any stationary set $S \subseteq \aleph_1$, $\diamond(S)$ is the assertion that there is a sequence $\{ h_\alpha : \alpha \in S \}$ of functions $h_\alpha : \alpha \to \aleph_1$ such that for any function $f : \aleph_1 \to \aleph_1$ the set $\{ \alpha \in S : f|\alpha = h_\alpha \}$ is stationary.

$\diamond^S$ is the assertion that $\diamond(S)$ holds for every stationary $S \subseteq \aleph_1$.

Thus, $\diamond(S)$ says that paths down the standard $\aleph_1$-$\aleph_1$-tree can be blocked just by removing one vertex from each level in $S$, and $\diamond^S$ says this can be done for every stationary set $S$.

We will force $\diamond^S$ by adding not just one diamond sequence as in Theorem 14.2, but more than $2^{\aleph_0}$ diamond sequences. The notion of forcing used in Theorem 14.2 actually verifies $\diamond(S)$ for every stationary $S$ in $\mathcal{M}$, so the idea is that if we add many diamond sequences at once then for every stationary $S$ in $\mathcal{M}[G]$, some of
Lemma 17.4. Let $S \subseteq \mathcal{M}$ be a subset of $\mathbb{R}_1$ such that $\mathcal{M} \models \text{"} S \text{ is stationary} \text{"}$ and let $P$ be the notion of forcing used in the proof of Theorem 14.2. Then $\diamond \,(S)$ is true in $\mathcal{M}[G]$, for any generic filter $G$.

Proof. Fix a generic filter $G$ and suppose $\diamond \,(S)$ fails in $\mathcal{M}[G]$. Let $(h_\alpha)$ be the sequence of functions $h_\alpha : \alpha \rightarrow \mathbb{R}_1^\mathcal{M}$ which constitute the union of $G$. Then we can find a function $f$ in $\mathcal{M}[G]$ from $\mathbb{R}_1^\mathcal{M}$ to itself and a subset $C \subseteq \mathbb{R}_1^\mathcal{M}$ in $\mathcal{M}[G]$ such that $\mathcal{M} \models \text{"} C \text{ is closed and unbounded, and } f|_\alpha \neq h_\alpha \text{ for any } \alpha \in C \cap S' \text{"}$. Let $\tau$ be a $P$-name for $f$ and let $\sigma$ be a $P$-name for $C$, and find $p \in G$ such that $p$ forces $\text{"} \tau \text{ is a function from } \mathbb{N}_1 \text{ to itself, } \sigma \text{ is a closed and unbounded subset of } \mathbb{N}_1, \text{ and } \tau \text{ restricted to } \alpha \text{ is not in the union of } \Gamma \text{ for any } \alpha \in \sigma \cap S' \text{"}$. Working in $\mathcal{M}$, carry out the construction given in the proof of Theorem 14.2 to obtain $q_0 < p$ of length $\alpha_0$ such that $q_0$ forces $\text{"} \bar{\alpha}_0 \in \sigma \text{ and } \tau \text{ restricted to } \bar{\alpha}_0 \text{ is in the union of } \Gamma \text{"}$. Then carry out the construction again to get $q_1 < q_0$ of length $\alpha_1$ with the same property, and iterate. We get a sequence $\{\alpha_\nu : \nu \in \mathbb{N}_1^\mathcal{M}\}$ which enumerates a closed unbounded subset $D$ of $\mathbb{N}_1$, together with elements $q_\nu \in P$ which force that $\bar{\alpha}_\nu$ is in $\sigma$ and $\tau$ restricted to $\bar{\alpha}_\nu$ is in the union of $\Gamma$. Since $S$ is stationary, $S \cap D \neq \emptyset$, so let $\alpha_{\nu^*} \in S \cap D$. We now reach a contradiction, because $q_{\nu^*}$ forces $\Gamma$ captures $\tau$ at the level $\bar{\alpha}_{\nu^*}$, but since it lies below $p$ it also forces that $\Gamma$ does not capture $\tau$ at any level in $\sigma \cap S$. We conclude that $\diamond \,(S)$ must hold in $\mathcal{M}[G]$.}

Next we need a version of the $\Delta$-systems lemma (Lemma 10.5) for countable sets.

Lemma 17.5. Say $2^{\aleph_0} = \aleph_\alpha$ and let $\kappa = \aleph_{\alpha + 1}$. Let $A$ be a family of $\kappa$ distinct countable subsets of a set of cardinality $\kappa$. Then there is a set $r$ and a subfamily $B \subseteq A$ of cardinality $\kappa$ such that $a \cap b = r$ for any distinct $a,b \in B$.

Proof. Without loss of generality, suppose $A$ is a family of subsets of the cardinal $\kappa$. We claim that there exists an ordinal $\gamma < \kappa$ such that for every $\delta > \gamma$, there is some set $a \in A$ which contains an ordinal larger than $\delta$ but no ordinals between $\gamma$ and $\delta$.

Suppose the claim fails. Then for every $\gamma < \kappa$ there exists $\delta > \gamma$ such that every set in $A$ either contains no ordinal larger than $\gamma$ or contains an ordinal between $\gamma$ and $\delta$. Create an increasing sequence $\gamma_\beta$, $\beta < \aleph_1$, by setting $\gamma_0 = 0$ and using the failure of the claim to find $\gamma_{\beta + 1} = \delta$ for every $\gamma_\beta = \gamma$. For every $\gamma < \kappa$ we have $\text{card}(\gamma) \leq 2^{\aleph_0}$, so there are at most $2^{\aleph_0}$ distinct countable subsets of $\gamma$ (§ 3, Exercise (e)). So for each $\beta < \aleph_1$, there are at most $2^{\aleph_0}$ sets in $A$ contained in $\gamma_\beta$, and hence there are at most $\aleph_1 \cdot 2^{\aleph_0} = 2^{\aleph_0}$ sets in $A$ that are contained in any $\gamma_\beta$. Since $A$ has cardinality $\kappa > 2^{\aleph_0}$, there must be some $a \in A$ that is not contained in any $\gamma_\beta$. But then by the construction of $\gamma_{\beta + 1}$ we have that $a$ contains an ordinal between $\gamma_\beta$ and $\gamma_{\beta + 1}$ for all $\beta < \aleph_1$, which is impossible since every element of $A$ is countable. This contradiction establishes the claim.

Now fix $\gamma < \kappa$ verifying the claim. Choose a sequence of sets $a_\beta \in A$, $\beta < \kappa$, by picking $a_0$ arbitrarily and for general $\beta$ using the lemma to find a set set $a_\beta \in A$ which contains no ordinal between $\gamma$ and $(\sup \bigcup_{\beta' < \beta} a_{\beta'}) + 1$. Then $\{a_\beta : \beta < \kappa\}$ is a subfamily of $A$ of $\kappa$ distinct countable sets, the intersection of any two of which is a countable subset of $\gamma$. But as we noted earlier, there are at most $2^{\aleph_0} < \kappa$ countable subsets of $\gamma$, so for some countable $r \subseteq \gamma$ we have $a \cap b = r$ for all distinct $a$ and $b$ in some subfamily $B$ of $\{a_\beta : \beta < \kappa\}$ of cardinality $\kappa$.

Lemma 17.6. Let $P$ be any notion of forcing, let $G$ be a generic filter of $P$, let $A$ be any set in $\mathcal{M}$, and let $\tau$ be a $P$-name such that $\mathcal{M}[G] \models \text{"} \text{val}_G(\tau) \subseteq A \text{"}$. Then there is a $P$-name $\sigma$ whose elements are all of the form $\langle x,p \rangle$ for $x \in A$ and $p \in P$, such that $\text{val}_G(\tau) = \text{val}_G(\sigma)$. If $\mathcal{M} \models \text{"} \text{card}(A) \leq 2^{\aleph_0} \text{ and every} \$
down-antichain in \( P \) has cardinality at most \( 2^{\aleph_0} \) then we can choose \( \sigma \) so that \( M \models \langle \sigma \rangle = \text{“}\sigma \text{ contains at most } 2^{\aleph_0} \text{ elements} \text{“} \).

**Proof.** Let \( \sigma \) be the set of all pairs \( (\bar{x}, p) \) such that \( x \in A, p \in P \), and \( p \models \bar{x} \in \tau \). It is an exercise to verify that \( \text{val}(\tau) = \text{val}(\sigma) \).

To prove the second assertion, working in \( M \), for each \( x \in A \) let \( S_x \) be the set of \( p \in P \) which force \( \bar{x} \in \tau \), and let \( T_x \) be a maximal down-antichain in \( S_x \). Then let \( \sigma' \) be the set of all pairs \( (\bar{x}, p) \) such that \( x \in A \) and \( p \in T_x \). If \( M \models \langle \text{card}(A) \rangle \) and \( \text{card}(T_x) \) are both at most \( 2^{\aleph_0} \) for all \( x \in A \), then \( M \models \langle \sigma' \rangle = \text{“}\sigma' \text{ contains at most } 2^{\aleph_0} \text{ elements} \text{“} \). The fact that \( \text{val}(\tau) = \text{val}(\sigma') \) is another exercise. \( \square \)

The \( P \)-name \( \sigma' \) in Lemma 17.6 is called a **nice name** for a subset of \( A \).

**Theorem 17.7.** Say \( M \models \langle \mathfrak{d}^{\aleph_0} = \aleph_0 \rangle \) and \( \alpha = \aleph_{\alpha + 1} \). Let \( P \) be the notion of forcing defined in \( M \) as all families of sequences \( \{ f^\delta : \delta \in A \text{ and } \gamma < \alpha \} \) such that \( A \) is a countable subset of \( \alpha \), \( \alpha < \aleph_1 \), and each \( f^\delta \) is a function from \( \gamma \) into \( \aleph_1 \). Then \( \diamondsuit^{\mathcal{S}} \) is true in \( M[G] \), for any generic filter \( G \) of \( P \).

**Proof.** Fix \( S \in M[G] \) such that \( M[G] \models \langle S \rangle \text{ is a stationary subset of } \aleph_1 \rangle \) and let \( \tau \) be a \( P \)-name for \( S \). It follows from Lemma 17.5 that \( M \models \langle P \rangle \text{ contains no down-antichains of cardinality greater than } 2^{\aleph_0} \rangle \) (exercise), so we can use Lemma 17.6 with \( A = \aleph_1 \) to find a nice name \( \sigma \) for \( S \) such that \( M \models \langle \sigma \rangle = \text{“}\sigma \text{ contains at most } 2^{\aleph_0} \text{ elements} \text{“} \).

Working in \( M \), for every pair \( (\bar{x}, p) \) in \( \sigma \) let \( A_p \) be the countable subset of \( \kappa \) such that \( p \) is a family of sequences \( f^\delta \) with \( \delta \in A_p \). Since \( \sigma \) contains at most \( 2^{\aleph_0} \) pairs, the union of all the \( A_p \) has cardinality at most \( 2^{\aleph_0} \). So there must exist an ordinal \( \delta_0 < \kappa \) that does not belong to any \( A_p \).

We have \( P \cong P_1 \times P_2 \) where \( P_1 \) consists of all elements of \( P \) for which \( \delta_0 \notin A \), and \( P_2 \) consists of all elements of \( P \) for which \( A = \{ \delta_0 \} \). Let \( G \cong G_1 \times G_2 \) be the corresponding decomposition of \( G \). Then \( \text{val}_{G_1}(\sigma) = \text{val}_{G}(\sigma) \) since any pair \( (\bar{x}, p) \) in \( \sigma \) satisfies \( p \in P_1 \), and hence \( S \in M[G_i] \). Since \( M[G] \models \langle S \rangle \text{ is stationary} \rangle \) it follows that \( M[G_1] \models \langle S \rangle \text{ is stationary} \rangle \) (exercise). Then \( M[G] = M[G_1][G_2] \) satisfies \( \diamondsuit(S) \) by Lemma 17.4, and as \( S \) was arbitrary we conclude that \( \diamondsuit^{\mathcal{S}} \) is true in \( M[G] \). \( \square \)

**Exercises**

(a) In the proof of Lemma 17.6, verify that \( \text{val}(\tau) = \text{val}(\sigma) \) and \( \text{val}(\tau) = \text{val}(\sigma') \).

(b) In the proof of Theorem 17.7, verify that \( M \models \langle P \rangle \) contains no down-antichains of cardinality greater than \( 2^{\aleph_0} \).

(c) In the proof of Theorem 17.7, show that \( M[G] \models \langle S \rangle \text{ is stationary} \rangle \) implies that \( M[G_1] \models \langle S \rangle \text{ is stationary} \rangle \). (Hint: show that if \( M[G_1] \models \langle C \rangle \) is closed and unbounded \rangle then \( M[G] \models \langle C \rangle \) is closed and unbounded \rangle.)

### 18. Application: The Whitehead problem, I

We work in ZFC. In this section all groups are abelian.

**Definition 18.1.** Let \( A \) be an abelian group.

(a) \( A \) is **free** if there is a set \( \{ g_i : i \in I \} \) of elements of \( A \) (a **basis** for \( A \)) such that every \( g \in A \) is uniquely expressible in the form

\[
g = n_1 g_{i_1} + \cdots + n_k g_{i_k}
\]

with \( i_1, \ldots, i_k \in I \) and \( n_1, \ldots, n_k \in \mathbb{Z} \).

(b) An **extension** of \( A \) by \( \mathbb{Z} \) is an abelian group \( B \) together with a surjective homomorphism \( \pi : B \rightarrow A \) with kernel isomorphic to \( \mathbb{Z} \), i.e., it is a short exact sequence

\[
0 \rightarrow \mathbb{Z} \rightarrow B \rightarrow A \rightarrow 0.
\]
It is trivial if \( B \cong A \oplus \mathbb{Z} \) and \( \pi \) is projection onto the first summand.

**Proposition 18.2.** Let \( A \) be a free abelian group. Then every extension of \( A \) by \( \mathbb{Z} \) is trivial.

**Proof.** Let \( \pi : B \to A \) be a surjective homomorphism with kernel \( \mathbb{Z} \). Fix a basis \( \{ g_i : i \in I \} \) for \( A \), and for each \( i \in I \) choose \( h_i \in \pi^{-1}(g_i) \). Let \( A' \) be the subgroup of \( B \) generated by the \( h_i \). Then it is straightforward to check that \( A' \cong A, A' \cap \ker \pi = \{0\} \), and \( A' + \ker \pi = B \). Thus \( B \cong A \oplus \mathbb{Z} \) and \( \pi \) is projection onto the first summand. \( \square \)

The idea of this proposition can be expressed more abstractly. An extension \( \pi : B \to A \) of \( A \) by \( \mathbb{Z} \) is trivial if and only if there is a homomorphism \( \rho : A \to B \) such that \( \pi \circ \rho = \text{id}_A \). (If \( B \cong A \oplus \mathbb{Z} \) and \( \pi \) is projection onto the first factor, the definition of \( \rho \) is obvious; if there is such a map \( \rho \), then \( B = \rho(A) + \ker \pi \cong A \oplus \mathbb{Z} \).) We say that \( \rho \) splits \( \pi \).

According to Proposition 18.2, every free abelian group has only trivial extensions by \( \mathbb{Z} \). The Whitehead problem asks: if \( A \) has only trivial extensions by \( \mathbb{Z} \), is it free?

The argument of Proposition 18.2 actually shows that any extension of a free abelian group by any abelian group is trivial, and the converse of this statement is true in ZFC: if all extensions of \( A \) by any abelian group are trivial, then \( A \) is free. But when \( A \) is countable, having only trivial extensions by \( \mathbb{Z} \) is enough:

**Theorem 18.3.** Let \( A \) be a countable abelian group and suppose all extensions of \( A \) by \( \mathbb{Z} \) are trivial. Then \( A \) is free.

We omit the proof of Theorem 18.3 (see Exercise (c)). Using this result, we will show \( \diamondsuit^S \) implies the same result when \( A \) has cardinality \( \aleph_1 \), a theorem due to Saharon Shelah. Shelah also proved that versions of \( \diamondsuit^S \) for arbitrary cardinals give the result for groups of arbitrary cardinality. Thus, it is relatively consistent with ZFC that any abelian group with only trivial extensions by \( \mathbb{Z} \) is free.

The next lemma can be proven using techniques from homological algebra, but we give an elementary proof. This proof uses an idea of Mohan Kumar.

**Lemma 18.4.** Let \( A \) be an abelian group, let \( A_0 \) be a subgroup of \( A \), and let \( \pi_0 : B_0 \to A_0 \) be an extension of \( A_0 \) by \( \mathbb{Z} \). Then \( \pi_0 \) embeds in an extension \( \pi : B \to A \) of \( A \) by \( \mathbb{Z} \).

**Proof.** Using Zorn’s lemma, it is enough to consider the case that \( A \) is generated by \( A_0 \) and one additional element \( a \). Suppose this is the case. If the cyclic subgroup of \( A \) generated by \( a \) does not intersect \( A_0 \), then \( A \cong A_0 \oplus \mathbb{Z} \) and we can define \( B = B_0 \oplus \mathbb{Z} \) and \( \pi(x \oplus m) = \pi_0(x) \oplus m \).

Otherwise, let \( n \) be the least positive integer such that \( na \in A_0 \), and write \( b = na \). Then fix \( b' \in B_0 \) such that \( \pi_0(b') = b \) and let \( B = B_0 \oplus \mathbb{Z}/I \) where \( I \) is the cyclic subgroup of \( B_0 \oplus \mathbb{Z} \) generated by \( b' \oplus n \). Define \( \pi : B \to A \) by \( \pi((x \oplus m) + I) = \pi_0(x) - ma \). This is well-defined since \( \pi_0(b') - na = b - na = 0 \). We can embed \( B_0 \) in \( B \) by the map \( x \mapsto (x \oplus 0) + I \), and the restriction of \( \pi \) to \( B_0 \) then agrees with \( \pi_0 \). The kernel of \( \pi \) consists of all \((x \oplus m) + I \in B\) such that \( \pi_0(x) = ma \). Since \( \pi_0(x) \in A_0 \) we must have \( m = nk \) for some integer \( k \), and then \( \pi_0(x) = mA = nka = kb \) implies that \( x = k(b' + z) \) for some \( z \in \ker \pi_0 \). That is,

\[
(x \oplus m) + I = (kb' + z \oplus nk) + I = (z \oplus 0) + I
\]

since \( kb' \oplus nk = k(b' \oplus n) \in I \), so that \( \ker \pi = \ker \pi_0 = \mathbb{Z} \). So \( \pi : B \to A \) is the desired extension of \( A \) by \( \mathbb{Z} \).

It immediately follows from Theorem 18.3 and Lemma 18.4 that if \( A \) has only trivial extensions by \( \mathbb{Z} \) then all countable subgroups of \( A \) are free.

**Lemma 18.5.** Let \( A \) be an abelian group, \( A_0 \) a subgroup of \( A \), and \( \rho_0 : A_0 \to A_0 \oplus \mathbb{Z} \) the standard splitting of the trivial extension of \( A_0 \) by \( \mathbb{Z} \). Suppose that the quotient group \( A/A_0 \) has a nontrivial extension by \( \mathbb{Z} \). Then the trivial extension of \( A_0 \) by \( \mathbb{Z} \) can be embedded in an extension of \( A \) by \( \mathbb{Z} \) no splitting of which restricts to \( \rho_0 \) on \( A_0 \).

35
Enumerate the elements of countable subgroups $B$ of $\pi$ underlying set of $A$.

Suppose the lemma fails. Then $\pi$ is not free (since $\alpha$ is free).

Proof. We now recursively construct a nested sequence of countable abelian groups $A$ containing $A_0$ by $\pi$.

Let $A = A/A_0$ and let $\pi' : B' \to A'$ be a nontrivial extension of $A'$ by $\pi$. Let $B$ be the subgroup of $A \oplus B'$ consisting of all elements of the form $x \oplus y$ such that $x + A_0 = \pi'(y)$, and define $\pi : B \to A$ by $\pi(x \oplus y) = x$. Then $\pi$ is surjective because $\pi'$ is surjective: for every $x \in A$ there exists $y \in B'$ such that $\pi'(y) = x + A_0$. The kernel of $\pi$ consists of all $x \oplus y$ such that $x = 0$ and $\pi'(y) = A_0$, i.e., it consists of all elements of the form $0 \oplus y$ for $y \in \ker \pi'$. So $\ker \pi = \ker \pi' = Z$. Thus $\pi : B \to A$ is an extension of $A$ by $B$.

$B$ contains $A_0 \oplus Z$, and restricting $\pi$ to this subgroup yields the trivial extension of $A_0$ by $Z$. Suppose the standard splitting $\rho_0 : A_0 \to A_0 \oplus Z$ defined by $\rho_0(x) = x \oplus 0$ extended to a splitting $\rho : A \to B$ of $\pi$. Then we could define a splitting $\rho' : A' \to B'$ of $\pi'$ by setting $\rho'(x + A_0) = y$ where $\rho(x) = x \oplus y$. This would be well-defined because for $x \in A_0$ we would have $\rho(x) = \rho_0(x) = x \oplus 0$, and it would be a splitting because $x \oplus y \in B$ implies $\pi'(y) = x + A_0$. This is impossible because $\pi'$ is a nontrivial extension of $A'$, so we conclude that $\rho_0$ does not extend to a splitting of $\pi$.

The next lemma contains the substance of the proof.

Lemma 18.6. Assume $\diamondsuit^S$ and let $A$ be a group of cardinality $\aleph_1$ all of whose extensions by $Z$ are trivial. Suppose $A = \bigcup_{1 \leq \alpha < \aleph_1} A_\alpha$ where the $A_\alpha$ are strictly nested countably infinite subgroups of $A$ such that $A_\alpha = \bigcup_{\beta < \alpha} A_\beta$ when $\alpha$ is a limit ordinal. Then $A_{\alpha+1}/A_\alpha$ is free for all $\alpha$ in some closed unbounded set $C \subseteq \aleph_1$.

Proof. Construct a tree as follows. The vertices at level $\alpha$ are all functions $f : A_\alpha \to N \times \alpha$ such that $f(A_\beta) \subseteq N \times \beta$ for all $\beta < \alpha$, with $g$ lying below $f$ if $g$ is an extension of $f$. Suppose the lemma fails; then the set $S \subseteq \aleph_1$ of values of $\alpha$ such that $A_{\alpha+1}/A_\alpha$ is not free is stationary. Use $\diamondsuit^S$ to choose a sequence of vertices $h_\alpha, \alpha \in S$.

We now recursively construct a nested sequence of countable abelian groups $C_\alpha, \alpha < \aleph_1$, such that the underlying set of $C_\alpha$ is the set $N \times \alpha$, together with surjections $\pi_\alpha : C_\alpha \to A_\alpha$ satisfying $\ker \pi_\alpha \cong Z$ and $\pi_\alpha|C_\beta = \pi_\beta$ for all $\beta < \alpha$.

Begin the construction by letting $\pi_1 : C_1 \to A_1$ be the trivial extension of $A_1$ by $Z$ and identifying the underlying set of $C_1$ with $N$ in any way. At limit levels let $C_\alpha = \bigcup_{\beta < \alpha} C_\beta$ and let $\pi_\alpha$ be the direct limit of the $\pi_\beta, \beta < \alpha$. At successor levels, we have two cases. If $\alpha \in S$ and $h_\alpha$ splits $\pi_\alpha$, use the fact that $A_{\alpha+1}/A_\alpha$ is not free (since $\alpha \in S$) plus Theorem 18.3 to find a nontrivial extension of $A_{\alpha+1}/A_\alpha$ by $Z$. Then apply Lemma 18.5 to get an extension $\pi_{\alpha+1} : C_{\alpha+1} \to A_{\alpha+1}$ by $Z$ which restricts to $\pi_\alpha$ on $C_\alpha$, but such that $h_\alpha$ does not extend to a splitting of $\pi_{\alpha+1}$. We may arrange that the underlying set of $C_{\alpha+1}$ is $N \times (\alpha + 1)$.

The other case is that $\alpha \notin S$ or $h_\alpha$ fails to split $\pi_\alpha$. Here we use Lemma 18.4 to embed $\pi_\alpha : C_\alpha \to A_\alpha$ in any extension $\pi_{\alpha+1} : C_{\alpha+1} \to A_{\alpha+1}$ of $A_{\alpha+1}$ by $Z$. Again, we may arrange that the underlying set of $C_{\alpha+1}$ is $N \times (\alpha + 1)$. This completes the description of the construction.

Let $C = \bigcup_{1 \leq \alpha < \aleph_1} C_\alpha$ and let $\pi : C \to A$ be the union of the maps $\pi_\alpha$. This is an extension of $A$ by $Z$, and since $A$ has only trivial extensions by $Z$, there is a splitting $\rho : A \to C$ of $\pi$. We have $\rho(A_\alpha) \subseteq C_\alpha$ for all $\alpha$ (exercise). By $\diamondsuit^S$ there therefore exists $\alpha \in S$ such that $\rho|A_\alpha = h_\alpha$. This puts us in the first case at that stage of the construction, so $h_\alpha$ does not extend to a splitting of $\pi_{\alpha+1}$. But $\rho|A_{\alpha+1}$ is just such a splitting, which is a contradiction. Thus $A_{\alpha+1}/A_\alpha$ could not fail to be free on a stationary set.

Lemma 18.7. Assume $\diamondsuit^S$ and let $A$ be a group of cardinality $\aleph_1$ all of whose extensions by $Z$ are trivial. Let $A_1$ be a countably infinite subgroup of $A$. Then there exists a countable subgroup $B_1$ of $A$ containing $A_1$ such that for any countable subgroup $B$ of $A$ containing $A_1$ the quotient $B/B_1$ is free.

Proof. Suppose the lemma fails. Then

(i) for any countable subgroup $B_1$ containing $A_1$ there exists a countable subgroup $B$ containing $B_1$ such that $B/B_1$ is not free.

Enumerate the elements of $A$ as $\{x_\alpha : \alpha < \aleph_1\}$. Now recursively construct a strictly nested sequence of countable subgroups $A_\alpha$ of $A$ such that (1) $A_\alpha = \bigcup_{\beta < \alpha} A_\beta$ when $\alpha$ is a limit ordinal; (2) using (i), $A_{\alpha+1}/A_\alpha$...
is not free for any limit ordinal $\alpha$; and (3) $x_\alpha \in A_{\alpha+2}$ for all $\alpha < \aleph_1$. By (3) we get $A = \bigcup_{1 \leq \alpha < \aleph_1} A_\alpha$, and then (2) contradicts Lemma 18.6.

**Theorem 18.8.** Assume $\diamondsuit$ and let $A$ be a group of cardinality $\aleph_1$ all of whose extensions by $\mathbb{Z}$ are trivial. Then $A$ is free.

**Proof.** By Lemma 18.7 we can decompose $A$ as a nested transfinite sequence $(A_\alpha)$, $1 \leq \alpha < \aleph_1$, in such a way that $A_{\alpha+1}$ is always chosen to have the property that $B/A_{\alpha+1}$ is free, and thus $B \cong A_{\alpha+1} \oplus B/A_{\alpha+1}$, for any countable subgroup $B$ of $A$ that contains $A_{\alpha+1}$. We cannot immediately guarantee this property at limit stages, but by Lemma 18.6 we can find a closed unbounded subset $C \subseteq \aleph_1$ such that $A_{\alpha+1}/A_\alpha$ is free for all $\alpha \in C$, so that $A_{\alpha+1} \cong A_\alpha \oplus A_{\alpha+1}/A_\alpha$. It follows that for any $\beta \geq \alpha + 1$ we have

$$A_\beta \cong A_{\alpha+1} \oplus A_\beta/A_{\alpha+1} \cong A_\alpha \oplus A_{\alpha+1}/A_\alpha \oplus A_\beta/A_{\alpha+1}$$

so that $A_\beta/A_\alpha \cong A_{\alpha+1}/A_\alpha \oplus A_\beta/A_{\alpha+1}$ is free. Now $C$ is order-isomorphic to $\aleph_1$, so by discarding indices not in $C$ and relabelling we may assume that $C = \aleph_1$. We then have that $A_\beta/A_\alpha$ is free whenever $\beta > \alpha$.

We can now recursively construct a sequence of subgroups $B_\alpha$ of $A$ such that $A_{\alpha+1} = A_\alpha \oplus B_\alpha$ for all $\alpha$. Letting $A_0 = \{0\}$, we then have $A = \bigoplus_{\alpha < \aleph_1} B_\alpha$ where each $B_\alpha$ is free, and this implies that $A$ is free.

**Exercises**

(a) In the proof of Lemma 18.6, verify that $\rho(A_\alpha) \subseteq C_\alpha$ for all $\alpha$.

(b) Let $A$ be a finitely generated abelian group and suppose all extensions of $A$ by $\mathbb{Z}$ are trivial. Prove that $A$ is free. (Use the structure theorem for finitely generated abelian groups.)

(c) Assume the countable version of Lemma 18.7: if $A$ is a countable abelian group with only trivial extensions by $\mathbb{Z}$, then any finitely generated subgroup $A_1$ of $A$ is contained in a finitely generated subgroup $B_1$ such that $B_1/B_1$ is free for any finitely generated subgroup $B$ containing $B_1$. Then prove Theorem 18.3. (Hint: adapt the proof of Theorem 18.8, using Exercise (b) in place of Theorem 18.3.)

**References**

**19. Two-stage iterated forcing**

A two-stage iterated forcing construction involves first choosing a notion of forcing $P$ in $\mathbb{M}$ and constructing $\mathbb{M}[G]$ where $G$ is a generic filter of $P$, then choosing a notion of forcing $Q$ in $\mathbb{M}[G]$ and constructing $\mathbb{M}[G][H]$ where $H$ is a generic filter of $Q$. Using a name for $Q$ in $\mathbb{M}$, it is always possible to compress this procedure into a single step.

**Definition 19.1.** Let $P$ be a notion of forcing in $\mathbb{M}$ and let $\pi, \leq_\pi$, and $1_\pi$ be $P$-names such that

$$1_P \Vdash \text{“$\leq_\pi$ is a preorder of $\pi$ with greatest element $1_\pi$”}.$$

Then $P * \pi$ is the notion of forcing whose underlying set is

$$\{ \langle p, \tau \rangle : p \in P, \tau \in \text{dom}(\pi), \text{ and } p \Vdash \tau \in \pi \}$$

and with $\langle p, \tau \rangle \leq \langle q, \sigma \rangle$ if $p \leq q$ and $p \Vdash \tau \leq_\pi \sigma$. The greatest element of $P * \pi$ is $\langle 1_P, 1_\pi \rangle$.

In general $P * \pi$ is not a partially ordered set, even if $P$ is partially ordered, because it is possible that $p$ forces $\tau = \sigma$ for distinct $P$-names $\tau$ and $\sigma$, and this would imply $\langle p, \tau \rangle \leq \langle p, \sigma \rangle$ and $\langle p, \sigma \rangle \leq \langle p, \tau \rangle$. 

37
Proposition 19.2. Let \( P \) and \( \alpha \) be as in Definition 19.1 and let \( K \) be a filter of \( P \ast \pi \) which is generic relative to \( M \). Let
\[
G = \{ p \in P : \langle p, 1 \rangle \in K \}
\]
and
\[
H = \{ \text{val}_G(\tau) : \langle 1, \tau \rangle \in K \}.
\]
Then \( G \) is a filter of \( P \) which is generic relative to \( M \), \( H \) is a filter of \( \text{val}_G(\pi) \) which is generic relative to \( M[G] \), and \( M[K] = M[G][H] \).

Proof. The fact that \( G \) is a filter of \( P \) which is generic relative to \( M \) is an exercise. To see that \( H \) is a filter of \( \text{val}_G(\pi) \), let \( \langle 1, \tau \rangle \in K \) and suppose \( \text{val}_G(\tau) \leq \text{val}_G(\sigma) \). Then some \( p \in G \) forces \( \tau \leq \sigma \), and since \( p \in G \) we have \( \langle p, 1 \rangle \in K \). Since \( K \) is a filter there must exist \( \langle p', \tau' \rangle \in K \) less than both \( \langle 1, \tau \rangle \) and \( \langle p, 1 \rangle \); then \( p' \) forces \( \tau' \leq \tau \) and (since it is less than \( p \) \( \tau \leq \sigma \), so \( p' \) forces \( \tau' \leq \sigma \) and hence \( \langle p', \tau' \rangle \leq \langle 1, \sigma \rangle \). We conclude that \( \langle 1, \tau \rangle \in K \) and hence \( \text{val}_G(\sigma) \in H \). This shows that \( H \) is upwards closed. It is directed downwards because if \( \langle 1, \tau \rangle \in K \) and \( \langle 1, \sigma \rangle \in K \) then there exists \( \langle p, \rho \rangle \in K \) such that \( p \) forces \( \rho \leq \tau \) and \( \rho \leq \sigma \). Then \( \langle 1, \rho \rangle \in K \) since \( K \) is upwards closed, so that \( \text{val}_G(\rho) \in H \), and \( \text{val}_G(\rho) \leq \text{val}_G(\pi) \) because \( p \in G \). So \( H \) is directed downwards.

The proof that \( H \) intersects every dense subset of \( \text{val}_G(\pi) \) in \( M[G] \) is essentially the same as the proof that \( G_2 \) is generic relative to \( M[G_1] \) in Theorem 17.2 (b). The proof that \( M[K] = M[G][H] \) is essentially the same as the proof that \( M[G] = M[G_1][G_2] \) in Theorem 17.2.

We will need the following fact about two-stage iterated forcing.

Proposition 19.3. Let \( P \) and \( \pi \) be as in Definition 19.1. Suppose \( M \models \text{"} P \text{ is c.c.c. \"} \) and \( 1_P \models \text{"} \pi \text{ is c.c.c. \"} \). Then \( M \models \text{"} P \ast \pi \text{ is c.c.c. \"} \).

Proof. Let \( \gamma \) be an ordinal in \( M \) and suppose \( \{ \langle p_\alpha, \tau_\alpha \rangle : \alpha < \gamma \} \) is an antichain in \( P \ast \pi \) in \( M \). Let \( G \) be a filter of \( P \) which is generic relative to \( M \) and let \( \sigma \) be the \( P \)-name consisting of all pairs \( \langle \alpha, p_\alpha \rangle \). We claim that the elements \( \text{val}_G(\tau_\alpha) \) for \( \alpha \in \text{val}_G(\sigma) \) constitute an antichain in \( \text{val}_G(\pi) \). Indeed, if \( \text{val}_G(\tau_\alpha) \) and \( \text{val}_G(\tau_\beta) \) had a common extension \( \text{val}_G(\rho) \) for some \( \alpha, \beta \in \text{val}_G(\sigma) \), then we could find \( p \in G \) which forces \( \rho \leq \tau_\alpha \) and \( \rho \leq \tau_\beta \). Since \( \alpha, \beta \in \text{val}_G(\sigma) \) we have \( p_\alpha, p_\beta \in G \), so we may assume \( p \leq p_\alpha \) and \( p \leq p_\beta \). But then \( \langle p, \rho \rangle \) must be a common extension of \( \langle p_\alpha, \tau_\alpha \rangle \) and \( \langle p_\beta, \tau_\beta \rangle \) in \( P \ast \pi \), a contradiction. This proves the claim.

Since \( 1_P \) forces \( \pi \text{ is c.c.c.} \) it must therefore force \( \sigma \text{ is countable} \). Now, working in \( M \), for each \( \alpha < \gamma \) choose \( q_\alpha \in P \) which forces \( \text{"} \alpha = \text{sup}(\sigma) \text{"} \), if any such \( q_\alpha \) exists. Then the set of all \( q_\alpha \) is an antichain in \( P \) in \( M \), so since \( M \models \text{"} P \text{ is c.c.c. \"} \) we must have that \( M \models \text{"} \beta \text{ is countable \"} \) where \( \beta \) is the supremum of all \( \alpha \) which are forced by some element of \( P \) to equal \( \text{sup}(\sigma) \). Since \( p_\alpha \models \text{"} \alpha \in \sigma \text{"} \), it follows that every \( \alpha < \gamma \) is less than \( \beta \), i.e., \( \gamma \leq \beta \). Thus \( M \models \text{"} \gamma \text{ is countable \"} \), so we conclude that \( M \models \text{"} P \ast \pi \text{ is c.c.c. \"} \).

Exercises
(a) In Proposition 19.2, prove that \( G \) is a filter of \( P \) which is generic relative to \( M \). Also check that \( H \) is generic relative to \( M[G] \).
(b) Let \( \langle p, \tau \rangle \in P \ast \pi \) and \( q \in P \). Prove that \( p \) is incompatible with \( q \) in \( P \) if and only if \( \langle p, \tau \rangle \) is incompatible with \( \langle q, 1 \rangle \) in \( P \ast \pi \).

20. Finite support iterations

We now generalize two-stage iterated forcing to sequential forcing constructions of arbitrary length. Typically this technique is used in such a way that each stage of the forcing construction destroys one particular counterexample of some sort, and the entire sequence of forcing constructions results in a model in which there are no counterexamples of the kind in question. In order for this to work we need to be able to destroy any single potential counterexample by forcing, and we also need to be able to arrange the sequential
construction so that all counterexamples are eventually handled, and no new counterexamples appear in the final model.

In iterated forcing constructions, successor stages always follow the two-stage construction, but there are different ways of handling limit stages. Here we present the most standard construction using “finite supports”.

**Definition 20.1.** Let $\alpha$ be an ordinal in $M$. An $\alpha$-stage finite support iterated forcing construction consists of (1) a sequence $\{P_\gamma : \gamma \leq \alpha\}$ in $M$ such that each $P_\gamma$ is a notion of forcing with preorder $\leq_\gamma$ and greatest element $1_\gamma$, and (2) a sequence $\{\pi_\gamma : \gamma < \alpha\}$ in $M$ such that each $\pi_\gamma$ is a $P_\gamma$-name, together with $P_\gamma$-names $\leq_\gamma$ and $1'_\gamma$ such that

$$1_\gamma \models "\leq_\gamma" \text{ is a preorder of } \pi_\gamma \text{ with greatest element } 1'_\gamma \text{.}$$

For every $\gamma$, every element of $P_\gamma$ must be a sequence $\bar{\rho} = \{\rho_\mu : \mu < \gamma\}$ with $\rho_\mu \in \text{dom}(\pi_\mu)$. (Thus $P_0$ has only one element, the empty sequence.) At successor stages, we require $P_{\gamma+1} = P_\gamma \ast \pi_\gamma$, so that its elements are just those sequences $\bar{\rho}$ of length $\gamma + 1$ such that the truncated sequence $\{\rho_\mu : \mu < \gamma\}$ belongs to $P_\gamma$ and forces $\rho_\gamma \in \pi_\gamma$, and the order relation is likewise as described in Definition 19.1. At limit stages we require that $P_\gamma$ consist of precisely those sequences $\bar{\rho}$ such that $\rho_\mu = 1'_\mu$ for all but finitely many $\mu < \gamma$, and $\bar{\rho}|\mu \in P_\mu$ for all $\mu < \gamma$. It is ordered by setting $\bar{\rho} \leq_\gamma \bar{\rho}'$ if $\bar{\rho}|\mu \leq_\mu \bar{\rho}'|\mu$ for all $\mu < \gamma$.

The next result is a partial analog of Proposition 19.2.

**Proposition 20.2.** Given an $\alpha$-stage finite support iterated forcing construction as in Definition 20.1, let $G$ be a filter of $P_\alpha$ which is generic relative to $M$. Then for every $\gamma < \alpha$, the set $G_\gamma$ of elements of $P_\gamma$ whose extension by $\{1_\mu : \mu \geq \gamma\}$ belongs to $G$ is a filter of $P_\gamma$ which is generic relative to $M$. Also, for every $\gamma < \alpha$ the set $H_\gamma$ of all $\text{val}(\bar{\rho})$ such that $\bar{\rho} \in \text{dom}(\pi_\gamma)$ and the sequence $\{\mu : \mu < \gamma\}$ followed by $\rho$ belongs to $G_{\gamma+1}$ is a filter of $\text{val}_{G_{\gamma}}(\pi_\gamma)$ which belongs to $M[G_{\gamma+1}]$ and is generic relative to $M[G_{\gamma}]$.

*Proof.* Exercise.

We also need the following two facts. We state the second one only in the special case that we need, $\alpha = \aleph_2$, but it can be generalized to the case that $\alpha$ is any regular cardinal. (A cardinal $\kappa$ is regular if a set of size $\kappa$ cannot be written as the union of fewer than $\kappa$ sets each of size less than $\kappa$. Every infinite successor cardinal, i.e., every $\aleph_{\alpha+1}$, is regular; $\aleph_\omega$ is the smallest infinite cardinal that is not regular.)

**Proposition 20.3.** Suppose $1_\gamma \models "\pi_\gamma \text{ is c.c.c."}$ for all $\gamma < \alpha$. Then $M \models "P_\alpha \text{ is c.c.c."}$

*Proof.* Working in $M$, we prove that $P_\gamma$ is c.c.c. by induction on $\gamma$. At successor stages this follows from Proposition 19.3. Now suppose $\gamma$ is a limit ordinal and let $A$ be an uncountable subset of $P_\gamma$. For $\bar{\rho} \in A$, say that $\{\gamma : \rho_\gamma \neq 1'_\gamma\}$ is the support of $\bar{\rho}$; then by Lemma 10.5 (the $\Delta$-systems lemma) we can find a finite set $r$ and an uncountable subset $B$ of $A$ such that $r$ is the intersection of the supports of any two distinct elements of $B$. Fix $\delta < \gamma$ such that $r \subseteq \delta$; then if $B$ were a down-antichain in $P_\delta$ it would easily follow that the restrictions of the elements of $B$ to $\delta$ would be a down-antichain in $P_\delta$. This contradicts the induction hypothesis that says $P_\delta$ is c.c.c. We conclude that $P_\gamma$ is c.c.c.

**Proposition 20.4.** Suppose $\alpha = \aleph_2^M$ and $M \models "\text{card}(A) = \aleph_2^M\text{,}"$ and let $B$ be a subset of $A$ in $M[G]$ for some generic filter $G$ of $P_\alpha$. Then in the notation of Proposition 20.2, $B$ belongs to $M[G_\gamma]$ for some $\gamma < \alpha$.

*Proof.* Let $\tau$ be a $P_\alpha$-name for $B$. Working in $M[G]$, for each $x \in B$ find $\bar{\rho}_x \in G$ which forces $\check{x} \in \tau$. Since $\text{card}(B) \leq \aleph_1^M = \aleph_1^{M[G]}$ and the support of each $\bar{\rho}_x$ is finite, there exists $\gamma < \alpha = \aleph_2^M = \aleph_2^{M[G]}$ such that the support of each $\bar{\rho}_x$ is contained in $\gamma$. Then

$$B = \{x \in A : \text{ some } \bar{\rho} \in G_\gamma \text{ extended by } \{1_\mu : \mu \geq \gamma\} \text{ forces } \check{x} \in \tau\}$$

belongs to $M[G_\gamma]$.
Exercises

(a) Prove Proposition 20.2.
(b) Let \(\tilde{\rho}, \tilde{\rho}' \in P_\alpha\) and choose \(\gamma < \alpha\) such that for every \(\mu \geq \gamma\), either \(\rho_\mu = 1_\mu\) or \(\rho'_\mu = 1'_\mu\). Prove that \(\tilde{\rho}\) and \(\tilde{\rho}'\) are incompatible in \(P_\alpha\) if and only if \(\tilde{\rho}|_\gamma\) and \(\tilde{\rho}'|_\gamma\) are incompatible in \(P_\gamma\).

21. Martin’s axiom

Definition 21.1. Martin’s axiom (MA) is the assertion that if \(P\) is a c.c.c. poset and \(\{D_\alpha\}\) is a family of fewer than \(2^{\aleph_0}\) dense subsets of \(P\), then there is a filter \(G\) of \(P\) which intersects every \(D_\alpha\).

In general, one cannot hope to find a filter that intersects \(2^{\aleph_0}\) dense sets. For example, let \(P\) be the infinite binary tree and for each branch \(\phi\) let \(D_\phi\) be the set of vertices not belonging to \(\phi\). Then each \(D_\phi\) is dense but there is no filter of \(P\) that intersects every \(D_\phi\) (exercise).

At the other extreme, it is a theorem of ZFC that for any countable family of dense subsets there is a filter that intersects them all (see Lemma 6.2). Thus, CH implies MA. But MA is also relatively consistent with \(\neg\)CH. Sometimes results proven using CH can actually be proven using only MA, and this implies that they are also relatively consistent with \(\neg\)CH. (For instance, this is true of the existence of pure states on \(B(H)\) which are not diagonalizable, proven in Theorem 13.5.)

In other cases, \(MA + \neg CH\) settles problems in a direction opposite to CH. So if some statement is proven relatively consistent using CH or \(\Diamond\), there is a reasonable chance that its negation can be proven relatively consistent using \(MA + \neg CH\).

We will force the relative consistency of \(MA + 2^{\aleph_0} = \aleph_2\). The idea of the proof is to carry out an \(\aleph_2\)-stage iterated forcing construction, where at each stage we add a filter which intersects \(\aleph_1\) dense subsets of a given c.c.c. poset. It suffices to verify MA for posets of cardinality \(\aleph_1\), so we only consider posets whose underlying set is the ordinal \(\aleph_1\). Each stage of the construction adds at most \(\aleph_2\) orderings of \(\aleph_1\), so a total of \(\aleph_2^\aleph_1 = \aleph_2\) orderings have to be handled and by arranging the construction carefully we are able to do this in \(\aleph_2\) steps.

First we verify that it is enough to check MA for posets of cardinality \(\aleph_1\).

Lemma 21.2. Assume \(2^{\aleph_0} = \aleph_2\) and suppose that for any family of \(\aleph_1\) dense subsets of any c.c.c. poset of cardinality \(\aleph_1\) there is a filter that intersects them all. Then Martin’s axiom is true.

Proof. Let \(P\) be a c.c.c. poset and let \(\{D_\alpha\}\) be a family of fewer than \(2^{\aleph_0} = \aleph_2\) dense subsets of \(P\). If this family is countable then there is a filter that intersects every \(D_\alpha\) (this was noted above). Thus we may assume the family has cardinality \(\aleph_1\). If \(P\) is countable then let \(P'\) be the disjoint union of \(P\) and \(\aleph_1\), giving \(\aleph_1\) its standard ordering and setting \(p < q\) for every \(p \in P\) and \(q \in \aleph_1\). Then \(P'\) has cardinality \(\aleph_1\) and the \(D_\alpha\) are also dense subsets of \(P'\), so by hypothesis there is a filter of \(P'\) that intersects every \(D_\alpha\), and its intersection with \(P\) is then a filter of \(P\) that intersects every \(D_\alpha\). So we may assume \(\text{card}(P) \geq \aleph_1\).

We will find a sub-poset \(Q \subset P\) whose cardinality is as most \(\aleph_1\), such that \(D_\alpha \cap Q\) is dense in \(Q\) for all \(\alpha\) and if \(p, q \in Q\) have a common extension in \(P\) then they have a common extension in \(Q\) (this implies that \(Q\) is c.c.c.). Having done this, we can apply the above reduction to find a filter \(H\) of \(Q\) that intersects each \(D_\alpha\), and then \(G = \{p \in P : p \geq q \text{ for some } q \in H\}\) is a filter of \(P\) that intersects each \(D_\alpha\), as desired.

We construct \(Q\) as follows. Let \(f : P \times P \to P\) be any function such that \(f(p, q)\) is a common extension of \(p\) and \(q\) provided such an extension exists (and otherwise \(f(p, q)\) may be arbitrary). Also, for each \(\alpha\) let \(g_\alpha : P \to P\) be any function such that for all \(p \in P\) we have \(g_\alpha(p) \leq p\) and \(g_\alpha(p) \in D_\alpha\). Now choose an element \(p_0\) of \(P\) and let \(Q\) be the smallest subset of \(P\) which contains \(p_0\) and is closed under \(f\) and the \(g_\alpha\). It is straightforward to check that \(\text{card}(Q) \leq \aleph_1\) and that \(Q\) has the desired properties.

Theorem 21.3. There is a notion of forcing \(P\) such that \(\text{M}[G] \models "MA + 2^{\aleph_0} = \aleph_2"\), for any generic filter \(G\) of \(P\).
Proof. Working in \( M \), let \( Q \) be the poset of bijections between subsets of \( P(\aleph_1) \) and \( \aleph_2 \) of size \( \aleph_1 \). Then \( M[H] \models "2^{\aleph_1} = \aleph_2" \), for any generic filter \( H \) of \( Q \). The proof of this is analogous to the proof of Theorem 9.3. For the remainder of the proof we work in \( M[H] \).

Let \( f \) be a function from \( \aleph_2 \) onto \( \aleph_2^2 \) such that the first coordinate of \( f(\alpha) \) is at most \( \alpha \), for all \( \alpha < \aleph_2 \). We now define an \( \aleph_2 \)-stage finite support iterated forcing construction, such that each \( P_\alpha \) is a c.c.c. preordering of \( \aleph_1 \), as follows. Suppose \( P_\beta, \pi_\beta, \) etc., have been constructed for all \( \beta < \alpha \). Then \( P_\alpha \) is determined by the definition of finite support iterated forcing. We must now define \( \pi_\alpha \).

Recall the notion of nice names introduced in Lemma 17.6. For every subset of \( \aleph_1^2 \) introduced in a generic extension using the notion of forcing \( P_\alpha \), there is a nice \( P_\alpha \)-name that evaluates to that subset. There are at most \( (\aleph_1^{\aleph_1})^{\aleph_1} = \aleph_2 \) nice names for subsets of \( \aleph_1^2 \); let \( \{ \sigma_\beta : \beta < \aleph_2 \} \) enumerate them. Say \( f(\alpha) = (\gamma, \delta) \).

Since \( \gamma \leq \alpha \), the \( P_\gamma \)-name \( \sigma_\gamma^f \) has already been defined. This may not be a name for a c.c.c. preorder, but we can find a \( P_\alpha \)-name \( \pi_\alpha \) such that \( 1_\alpha \) forces "\( \pi_\alpha \) is a c.c.c. preordering of \( \aleph_1 \) with a greatest element, such that if \( \sigma_\gamma^f \) is also a c.c.c. preordering of \( \aleph_1 \) with a greatest element then \( \pi_\alpha = \sigma_\gamma^f \)". This defines \( \pi_\alpha \), and the construction may proceed.

Let \( G \) be an \( M[H] \)-generic filter of \( P_{\aleph_2} \); we claim that \( M[H][G] \models "\text{MA} + 2^{\aleph_0} = \aleph_2"." First, \( P_{\aleph_2} \) is c.c.c. by Proposition 20.2, so \( \aleph_2^M[H] = \aleph_2^{M[H][G]} \). Work in \( M[H][G] \). By a nice name argument similar to the one used above, there are at most \( \aleph_2 \) nice \( P_{\aleph_2} \)-names for subsets of \( \aleph_1 \), so \( 2^{\aleph_0} \leq \aleph_2 \). By Lemma 21.2, in order to verify MA it is enough to show that for any family of \( \aleph_1 \) dense subsets of any poset of cardinality \( \aleph_1 \) there is a filter that intersects them all. By Proposition 20.4, any ordering of \( \aleph_1 \) that appears in the final \( \aleph_2 \)-stage iterated forcing construction, and any family of \( \aleph_1 \) dense subsets of this ordering, already appear at some intermediate stage. Thus the ordering would have been represented by some nice \( P_\gamma \)-name \( \sigma_\gamma^f \), and there would have been some \( \alpha < \aleph_2 \) such that \( \alpha \geq \gamma \) and \( f(\alpha) = (\gamma, \delta) \). We may also assume that the \( \aleph_1 \) dense subsets have appeared by stage \( \alpha \) and the forcing at that stage would then have added a filter that intersects them all. Thus such a filter exists in the final generic extension.

We already showed that \( 2^{\aleph_0} \leq \aleph_2 \). We cannot have \( 2^{\aleph_0} = \aleph_1 \) because we have shown that for any \( \aleph_1 \) dense subsets of a c.c.c. poset there is a generic filter that intersects them all (see the comment immediately following Definition 21.1). So \( 2^{\aleph_0} = \aleph_2 \).

Finally, let \( P = Q \ast \pi \) where \( \pi \) is a \( Q \)-name for \( P_{\aleph_2} \).

**Exercises**

(a) In the example stated just after Definition 21.1, prove that no filter intersects every \( D_\varphi \).

(b) In the proof of Theorem 21.3, show that \( M[H] \models "2^{\aleph_1} = \aleph_2.""

### 22. Application: Suslin’s problem, II

Recall (Definition 15.1) that a Suslin line is a totally ordered set that is dense, unbounded, complete, and c.c.c. but not order-isomorphic to \( \mathbb{R} \), and **Suslin’s problem** asks whether Suslin lines exist. Also recall that the existence of a Suslin line is equivalent to the existence of a **Suslin tree** (Definition 15.2), which is a tree of height \( \aleph_1 \) such that all branches and antichains are countable (Lemma 15.4).

We proved (Theorem 15.5) that the diamond principle implies the existence of Suslin lines. Now we show that Martin’s axiom implies there are no Suslin lines.

**Theorem 22.1.** Assume MA. Then Suslin lines do not exist.

**Proof.** By Lemma 15.4, it will suffice to show that normal Suslin trees do not exist. Suppose to the contrary that \( T \) is a normal Suslin tree. Since all antichains are countable, \( T \) is c.c.c. For each \( \alpha < \aleph_1 \), let \( D_\alpha \) be the set of all vertices of height at least \( \alpha \). Then each \( D_\alpha \) is dense because every vertex has descendents at every level. By MA, there is a filter \( G \) of \( T \) that intersects each \( D_\alpha \). But then \( G \) is an uncountable branch, a contradiction.\[\square\]
We now give two other basic applications of Martin’s axiom.

**Theorem 22.2.** Assume MA. Then any subset of \( R \) of cardinality less than \( 2^{\aleph_0} \) has measure zero.

**Proof.** Let \( S \subseteq R \) and suppose \( \text{card}(S) < 2^{\aleph_0} \). Fix \( \epsilon > 0 \) and let \( P \) be the set of all open subsets \( U \) of \( R \) such that (1) \( U \) is a union of finitely many open intervals with rational endpoints and (2) the measure of \( U \) is less than \( \epsilon \). Order \( P \) by reverse inclusion; then \( P \) is c.c.c. because it is countable. Also, for each \( r \in S \) let \( D_r \) be the set of all \( U \) in \( P \) which contain \( r \); this is a dense subset of \( P \) since for any \( U \in P \) an open interval \( I \) with rational endpoints that contains \( r \) can be found which is small enough that the measure of \( U \cup I \) is still less than \( \epsilon \). By MA there is a generic filter of \( P \) which intersects every \( D_r \). Its union is then an open set of measure at most \( \epsilon \) which contains \( S \). Since \( \epsilon \) was arbitrary, we conclude that \( S \) has measure zero. \( \blacksquare \)

Recall that a subset of \( R \) is **meager** if it is a countable union of nowhere-dense sets.

**Theorem 22.3.** Assume MA and let \( \{ C_\alpha : \alpha < \kappa \} \) be a family of fewer than \( 2^{\aleph_0} \) meager subsets of \( R \). Then \( \bigcup C_\alpha \) is meager.

**Proof.** Let \( P \) be the set of all finite sequences of ordered pairs \( \langle U, E \rangle \) such that (1) \( U \) is a finite union of open intervals with rational endpoints; (2) \( E \) is a finite subset of \( \kappa \); and (3) \( U \) is disjoint from \( \bigcup_{\alpha \in E} C_\alpha \). Order \( P \) by setting \( q \preceq p \) if the sequence \( q \) is at least as long as the sequence \( p \) and for every \( \langle U, E \rangle \) in \( p \) the corresponding \( \langle U', E' \rangle \) in \( q \) satisfies \( U \subseteq U' \) and \( E \subseteq E' \).

\( P \) is c.c.c. because any uncountable subset of \( P \) contains an uncountable subset all of whose elements are sequences of the same length \( n \), and this contains an uncountable subset all of whose elements involve the same sequence of \( U \)'s (since there are only countably sequences of \( U \)'s of length \( n \)); but any \( p \) and \( q \) of the same length with the same \( U \)'s are compatible.

For each \( \alpha < \kappa \), the set \( D_\alpha \) of \( p \in P \) which contain an ordered pair \( \langle U, E \rangle \) such that \( \alpha \in E \) is dense. Also, for each open interval \( I \) with rational endpoints and each \( i \) the set \( D_{I,i} \) of \( p \in P \) whose \( i \)th ordered pair \( \langle U, E \rangle \) satisfies \( U \cap I \neq \emptyset \) is dense. There are \( \kappa \) dense sets of the first type and \( \aleph_0 \) dense sets of the second type, so by MA there is a filter \( G \) which intersects all of the above dense sets.

For each \( i \in \mathbb{N} \) let \( V_i \) be the union of all \( U \) such that \( \langle U, E \rangle \) is the \( i \)th ordered pair in some \( p \in G \) (for some \( E \)). Since \( G \cap D_{I,i} \neq \emptyset \) for all \( I \), it follows that \( V_i \) is a dense open subset of \( R \). Also, since \( G \cap D_\alpha \neq \emptyset \), for each \( \alpha < \kappa \) we can find \( \langle U, E \rangle \in p \in G \) such that \( \alpha \in E \); if this is the \( i \)th pair in \( G \) then \( V_i \cap A_\alpha = \emptyset \). So \( \bigcap V_i \) is a countable intersection of dense open sets whose complement contains every \( C_\alpha \). Thus \( \bigcup C_\alpha \) is meager. \( \blacksquare \)

**Exercises**

(a) Assuming \( MA + \neg \text{CH} \), prove that any union of \( \aleph_1 \) measure zero subsets of \( R \) is a measure zero subset of \( R \).

---

**23. Application: The Whitehead problem, II**

Now we show that \( MA + \neg \text{CH} \) implies that there is a counterexample to Whitehead’s problem, i.e., an abelian group with only trivial extensions by \( Z \) that is not free. This proof is also due to Shelah.

Shelah’s example is defined as follows. It has generators \( a_\alpha \) for all \( \alpha < \aleph_1 \) and \( b_\alpha^n \) for every limit ordinal \( \alpha < \aleph_1 \) and every \( n \in \mathbb{N} \). For each limit ordinal \( \alpha \) choose a sequence \( (\alpha_n) \) of ordinals which increase to \( \alpha \) and include the relation

\[
    b_\alpha^n = a_\alpha + 2b_\alpha^{n+1}
\]

for all \( n \in \mathbb{N} \). Let \( G \) be the abelian group defined by these generators and relations.

For each \( \alpha < \aleph_1 \) let \( G_\alpha \) be the subgroup of \( G \) generated by all \( a_\beta \) with \( \beta < \alpha \) and all \( b_\beta^n \) with \( \beta \leq \alpha \) a limit ordinal and \( n \in \mathbb{N} \). Note that \( \bigcup_{\beta < \alpha} G_\beta \) does not equal \( G_\alpha \) when \( \alpha \) is a limit ordinal.

**Lemma 23.1.** \( G \) is not free.
Proof. Suppose $G$ is free and let $B$ be a basis. Inductively define a sequence of ordinals $\alpha_n$ as follows. Let $\alpha_0 = 0$. Given $\alpha_n$, $G_{\alpha_n}$ is a countable subgroup of $G$ so it is contained in the span of a countable subset $B'$ of $B$. Find $\alpha_{n+1}$ such that $G_{\alpha_{n+1}}$ contains $B'$.

Let $\alpha = \sup \alpha_n$ and let $G'_\alpha = \bigcup_n G_{\alpha_n}$. Then $G'_\alpha$ is spanned by $G'_\alpha \cap B$, so $G = G'_\alpha \oplus G/G'_\alpha$ and both summands are free. However, this is impossible because the nonzero element $b^1_\alpha + G'_\alpha$ in $G/G'_\alpha$ satisfies

$$b^1_\alpha + G'_\alpha = 2b^1_\alpha + G'_\alpha = 4b^2_\alpha + G'_\alpha = \cdots,$$

contradicting the fact that $G/G'_\alpha$ is free. We conclude that $G$ is not free.

Lemma 23.2. $G/\alpha G$ is free for all $\beta < \alpha < \aleph_1$.

Proof. Exercise.

A subgroup $H$ of a torsion-free group is pure if $na \in H$ implies $a \in H$, for any $n \in \mathbb{N}$. We need the following fact from group theory: any subgroup of a free abelian group is free.

Let $A$ be an abelian group and let $\pi : A \to G$ be a surjective homomorphism with kernel $\mathbb{Z}$. Define $P$ to be the poset of all homomorphisms $\rho : H \to A$ such that $H$ is a finitely generated pure subgroup of $G$ and $\pi \circ \rho = \text{id}_H$, with $\rho \leq \rho'$ if $\rho$ is an extension of $\rho'$.

Lemma 23.3. $P$ is c.c.c.

Proof. Let $S \subseteq P$ be uncountable. We claim that there is a pure free subgroup $H$ of $G$ which contains the domains of uncountably many $\rho \in S$. This is enough because if $B$ is a basis for $H$, then the domain of any $\rho$ contained in $H$ is contained in the span of a finite subset $B_\rho$ of $B$. By the $\Delta$-systems lemma (Lemma 10.5) there is an uncountable family $S'$ of $\rho \in S$ and a finite set $B_0 \subseteq B$ such that $B_\rho \cap B_{\rho'} = B_0$ for all distinct $\rho, \rho' \in S'$. For each $\rho \in S'$ let $\tilde{\rho}$ be an extension of $\rho$ to the span of $B_\rho$ (this is possible because the domain of $\rho$ is pure, so that span($B_\rho$)/dom($\rho$) is free by the structure theorem for finitely generated abelian groups). Then there are only countably many possible functions $\tilde{\rho}|_{B_0}$, so some distinct $\tilde{\rho}, \tilde{\rho}' \in S'$ have the same restriction to $B_0$ and hence they have a common extension to the span of $B_\rho \cup B_{\rho'}$. Thus $\rho$ and $\rho'$ are compatible, and we conclude that $P$ is c.c.c.

To prove the claim, find $n \in \mathbb{N}$ such that the domains of uncountably many $\rho \in S$ have bases of size $n$. Let $S'$ be the set of all such $\rho$. Then let $H_0$ be a maximal pure subgroup of $G$ with the property that $H_0 \subseteq \text{dom}(\rho)$ for uncountably many $\rho \in S'$. Let $T$ be the set of all $\rho \in S'$ whose domain contains $H_0$.

Recursively define homomorphisms $\rho_\alpha \in T$ and countable free pure subgroups $H_\alpha$ of $G$ for $\alpha < \aleph_1$ as follows. At successor stages, suppose $H_\alpha$ has been defined and let $H_\alpha \subseteq G'_{\alpha'}$. For all but countably many $\rho \in T$ we have $\text{dom}(\rho) \cap G'_{\alpha'} = H_0$. (Otherwise, since $G_{\alpha'}$ is countable, some $a \in G_{\alpha'} - H_0$ would be contained in the domains of uncountably many $\rho \in T$ and this would contradict maximality of $H_0$.) So choose $\rho_\alpha \in T$ distinct from all $\rho_\beta$ for $\beta < \alpha$ such that $\text{dom}(\rho_\alpha) \cap G_{\alpha'} = H_0$. Also let $H_{\alpha+1}$ be the smallest pure subgroup of $G$ that contains $H_\alpha$ and $\text{dom}(\rho_\alpha)$. If $H_{\alpha+1} \subseteq G_{\alpha''}$ then $H_{\alpha+1}/H_\alpha$ is isomorphic to a subgroup of $G_{\alpha''}/G_{\alpha'}$, which is free, so that freeness of $H_\alpha$ implies that $H_{\alpha+1}$ is also free.

At limit stages let $H_\alpha = \bigcup_{\beta < \alpha} H_\beta$. Since $H_{\beta+1}/H_\beta$ is free for all $\beta < \alpha$, it follows that $H_\alpha$ is free just as in the proof of Theorem 18.8. Also, purity of $H_\alpha$ trivially follows from purity of all $H_\beta$ for $\beta < \alpha$.

Finally, let $H = \bigcup_{\alpha < \aleph_1} H_\alpha$. Then $H$ is free and pure just as above. It contains $\text{dom}(\rho_\alpha)$ for all $\alpha < \aleph_1$, so the claim is proven.

Theorem 23.4. Assume MA + ¬ CH. Then $G$ is a group of cardinality $\aleph_1$ that is not free and all of whose extensions by $\mathbb{Z}$ are trivial.

Proof. $G$ is not free by Lemma 23.1. Let $\pi : A \to G$ be an extension by $\mathbb{Z}$ and let $P$ be the poset defined just before Lemma 23.3. We must show that $\pi$ splits.

43
For each $a \in G$ let $D_a$ be the set of all $\rho \in P$ whose domain contains $a$. We claim that $D_a$ is dense. To see this, let $\rho \in P$ and let $G_\alpha$ contain $a$ and the domain of $\rho$. Let $\mathcal{B}$ be a basis for $G_\alpha$ and let $\mathcal{B}_0$ be a finite subset of $\mathcal{B}$ whose span contains $a$ and the domain of $\rho$. Let $H$ be the span of $\mathcal{B}_0$; then $H/\text{dom}(\rho)$ is free, so we can choose a basis and extend $\rho$ to a splitting of $\pi|_{\pi^{-1}(H)} : \pi^{-1}(H) \to H$ one basis element at a time (cf. the proof of Proposition 18.2). This shows that $\rho$ has an extension in $D_a$.

Since $\text{card}(G) = \aleph_1 < 2^{\aleph_0}$, Martin’s axiom implies that there is a filter $F$ of $P$ that intersects every $D_a$. The union of $F$ is then a homomorphism from $G$ to $A$ that splits $\pi$, as desired.

Exercises
(a) Prove Lemma 23.2.
